(Received 9 March 1998)

We study the effect of umklapp scattering on the magnetic-field-induced spin-density-wave (FISDW) phases which are experimentally observed in the quasi-one-dimensional organic conductors of the Bechgaard salts family. Within the framework of the quantized nesting model, we show that the transition temperature is determined by a modified Stoner criterion which includes the effect of umklapp scattering. We determine the SDW polarization (linear or circular) by analyzing the Ginzburg-Landau expansion of the free energy. We also study how umklapp processes modify the quantum Hall effect (QHE) and the spectrum of the FISDW phases. We find that umklapp scattering stabilizes phases which exhibit a sign reversal of the QHE, as experimentally observed in the Bechgaard salts. These “negative” phases are characterized by the simultaneous existence of two SDW’s with comparable amplitudes. As the umklapp scattering strength increases, they may become helicoidal (circularly polarized SDW’s). The QHE vanishes in the helicoidal phases, but a magnetoelectric effect appears. These two characteristic properties may be utilized to detect the magnetic-field-induced helicoidal SDW phases experimentally. [S0163-1829/98/08937-1]

I. INTRODUCTION

The organic conductors of the Bechgaard salts family (TMTSF)$_2$X (where TMTSF stands for tetramethyltetraselenafulvalene) exhibit a rich phase diagram when temperature, magnetic field, or pressure are varied. In three members of this family ($X=\text{ClO}_4$, $\text{PF}_6$, $\text{ReO}_4$), a moderate magnetic field above several Tesla destroys the metallic phase and induces a series of spin-density-wave (SDW) phases separated by first-order phase transitions. Because of a strong quasi-one-dimensional (1D) anisotropy (the typical ratio of the electron transfer integrals in the three crystal directions is $t_a : t_b : t_c = 3000 : 300 : 10$ K), the Fermi surfaces of these materials are open. According to the so-called quantized nesting model (QNM), the formation of the magnetic-field-induced spin-density-wave (FISDW) phases results from an interplay between the nesting properties of the Fermi surface and the quantization of the electronic orbits in magnetic field. The wave vector of a FISDW adjusts itself to the magnetic field so that unpaired electrons completely fill an integer number of Landau levels, thus the Hall effect is quantized. The standard QNM predicts the Hall plateaus of the quantum Hall effect (QHE) at integer number of Landau levels, which leads to a half-filled band for the holes so that umklapp processes transferring $4k_F=2\pi/a$ are possible ($k_F$ being the Fermi wave vector of the holes, and $a$ the lattice spacing along the chains). Therefore, a quasi-1D g-ology description of the FISDW phases should include not only forward ($g_2$) and backward ($g_1$) scattering amplitudes, but also umklapp scattering amplitude ($g_3$). Since the dimerization is weak, we expect the umklapp scattering amplitude $g_3$ to be small. Nevertheless, we shall show in this paper that very weak umklapp processes can have drastic effects on the low-temperature phase diagram.

In the next section we obtain the FISDW transition temperature in the random-phase approximation (RPA) and discuss the phase diagram. In absence of umklapp scattering, the instability of the metallic phase corresponds to the formation of a SDW with a quantized longitudinal wave vector $Q^{(N)}_z=2k_F+NG$ ($N$ integer) where $G=eHb/h$ is a magnetic wave vector (with $H$ the magnetic field, $b$ the inter-chain spacing, and $-e$ the electron charge). As the field varies, the value of the integer $N$ changes (its sign remaining the same), which leads to a cascade of FISDW phases separated by first-order transitions. The integer $N$ also determines

achieved by decreasing the applied pressure. The helicoidal phases are characterized by a vanishing QHE and a kinetic magnetoelectric effect. In this paper we study the effect of umklapp processes on the FISDW phases within the framework of the QNM. We discuss in more detail the results reported in Ref. 15, and address issues not considered in the latter. The effect of umklapp scattering on the FISDW phases was studied before by Lebed’ using rather crude approximations, but the helicoidal phases and the sign reversals of the QHE were not discussed.

In Bechgaard salts, complete charge transfer from the molecules TMTSF to the anions X leads to a conduction band that is quarter-filled in terms of holes. A dimerization along the $x$ axis induces a gap in the electronic spectrum. This results in a half-filled band for the holes so that umklapp processes transferring $4k_F=2\pi/a$ are possible ($k_F$ being the Fermi wave vector of the holes, and $a$ the lattice spacing along the chains). Therefore, a quasi-1D g-ology description of the FISDW phases should include not only forward ($g_2$) and backward ($g_1$) scattering amplitudes, but also umklapp scattering amplitude ($g_3$). Since the dimerization is weak, we expect the umklapp scattering amplitude $g_3$ to be small. Nevertheless, we shall show in this paper that very weak umklapp processes can have drastic effects on the low-temperature phase diagram.

In the next section we obtain the FISDW transition temperature in the random-phase approximation (RPA) and discuss the phase diagram. In absence of umklapp scattering, the instability of the metallic phase corresponds to the formation of a SDW with a quantized longitudinal wave vector $Q^{(N)}_z=2k_F+NG$ ($N$ integer) where $G=eHb/h$ is a magnetic wave vector (with $H$ the magnetic field, $b$ the inter-chain spacing, and $-e$ the electron charge). As the field varies, the value of the integer $N$ changes (its sign remaining the same), which leads to a cascade of FISDW phases separated by first-order transitions. The integer $N$ also determines
the quantum Hall conductivity: $\sigma_{xy} = -2Ne^2/h$ per one layer of the TMTSF molecules. In presence of umklapp scattering, two SDW’s with quantized longitudinal wave vectors $Q_x^{(N)}$ and $Q_x^{(-N)}$ form simultaneously. We label each FISDW phase by the integer $N$ such that the SDW with wave vector $Q_x^{(N)}$ has the largest amplitude. We find that the transition temperature $T_c^{(N)}$ is determined by a modified Stoner criterion that includes the effect of umklapp scattering. We calculate $T_c^{(N)}$ numerically as a function of $g_3$ and the detailed geometry of the Fermi surface. In order to keep our discussion of the phase diagram compact, we use some results that are proved in subsequent sections. We find that weak umklapp scattering ($g_3/g_2$ a few percent) can lead to a FISDW cascade with both positive and negative values of $N$. Since the quantum Hall conductivity is still determined by the integer $N$, $\sigma_{xy} = -2Ne^2/h$ (Sec. VI), this leads to sign reversals of the QHE as the magnetic field varies. The negative phases may become helicoidal (i.e., with a circular polarization of the SDWs) (Sec. IV). The helicoidal phases are characterized by a vanishing QHE and the longitudinal electron dispersion is linearized in one-dimensional chains of TMTSF. In Eq. (2.1), the longitudinal electron dispersion law in the Begaard salts is approximated as (we take $\hbar = k_B = 1$ throughout the paper, and the Fermi energy $\mu$ is chosen as the origin of the energies)

$$E(k_x, k_y) = v_F(k_x) - k_x + t_{1}(k_x, b),$$

(2.1)

where $k_x$ and $k_y$ are the electron momenta along and across the one-dimensional chains of TMTSF. In Eq. (2.1), the longitudinal electron dispersion is linearized in $k_x$, in the vicinity of the two one-dimensional Fermi points $\pm k_F$, and $v_F = 2\alpha t_0 \sin(k_F a)$ is the corresponding Fermi velocity. The function $t_{1}(u)$, which describes the propagation in the transverse direction, is periodic: $t_{1}(u) = t_{1}(u + 2\pi)$. It can be expanded in Fourier series

$$t_{1}(u) = -2t_0 \cos(u) - 2t_{2b} \cos(2u) - 2t_{3b} \cos(3u) - 2t_{4b} \cos(4u) \cdots .$$

(2.2)

If we retain only the first harmonic ($t_0$), we obtain a Fermi surface with perfect nesting at $(2k_F, \pi/2h)$. The other harmonics $t_{2b}, t_{3b}, \cdots$ generate deviations from the perfect nesting. They have been introduced in order to keep a realistic description of the Fermi surface despite the linearization around $\pm k_F$. In the following, we shall retain only $t_0$, $t_{2b}$, and $t_{4b}$ (as we shall show, $t_{3b}$ does not play an important role in our mechanism and can be discarded). We do not consider the electron dispersion along the $z$ axis, because it is not important in the following (its main effect is to introduce a 3D threshold field below which the FISDW cascade is suppressed).

The effect of the magnetic field along the $z$ axis is taken into account via the Peierls substitution $k \rightarrow i\mathbf{\nabla} - e\mathbf{A}$. (The charge $e$ is positive since the actual carriers are holes.) Following Ref. 21, we use the gauge $\mathbf{A} = (-Hy, 0, 0)$. Considering also electron-electron interactions, we obtain the Hamiltonian $H = H_0 + H_{\text{int}}$ with

$$H_0 = \sum_{\alpha, \sigma} \int d^2r \psi_\alpha^\dagger(r) [v_F(-i\alpha \partial_\alpha - k_F)] \psi_\alpha(r) + \alpha m \omega_c + t_{1}(-ib \partial_\sigma) + \sigma \mu_b H \psi_\alpha(r),$$

(2.3)

$$H_{\text{int}} = \frac{g_2}{2} \sum_{\alpha, \sigma, \sigma'} \int d^2r \psi_\alpha^\dagger(r) \psi_{\sigma'}^\dagger(r) \psi_{\alpha'}(r) \psi_{\sigma}(r) + \frac{g_3}{2} \sum_{\alpha, \sigma} \int d^2r e^{-i\alpha k_F \cdot \mathbf{r}} \psi_\alpha^\dagger(r) \psi_{\alpha}^\dagger(r) \psi_{\alpha}(r) \psi_{\sigma}(r).$$

Here $\psi_{\alpha}(r)$ are fermionic operators for right ($\sigma = +$) and left ($\sigma = -$) moving particles. $\sigma = +(-)$ for $\uparrow$ ($\downarrow$) spin. We use the notation $\mathbf{r} = (x, mb)$ ($m$ integer), $\int d^2r = b \sum_m dx$ and $\tilde{a} = -a$, $\tilde{\sigma} = -\sigma$.

Apart from the Zeeman term $\sigma \mu_b H$ ($\mu_b$ is the Bohr magneton), and we take the electron gyromagnetic factor $g$ equal to 2), the magnetic field introduces the additional term $\alpha m \omega_c$, where $\hat{m}$ is the (discrete) position operator in the $y$ direction. $\omega_c = G \nu_F = eHb \nu_F$.

The interacting part of the Hamiltonian contains two terms corresponding to forward ($g_2$) and umklapp ($g_3$) scattering. For repulsive interactions $g_2, g_3 \gg 0$. We do not consider backward scattering ($g_1$), since it does not play any role in the mean-field theory of the FISDW phases.

### A. Bare susceptibility

The one-particle eigenstates of $H_0$ were obtained in Ref. 21 in the particular case where $t_{1}(u) = -2t_0 \cos(u)$. The extension to a general $t_{1}(u)$ is straightforward, and we only quote the final result. The eigenstates and the spectrum can be written as
EFFECT OF UMKLAPP SCATTERING ON THE...

\[ \chi^{(0)}_{\alpha}(\mathbf{q}, \omega) = \sum_n \tilde{I}^2_n(q_x) N_G(q_x - \alpha n G, \omega), \]

where \( N_G(q_x, \omega) \) is the one-particle Green’s function. \( \omega = \pi T(n + 1) (n \text{ integer}) \) is a fermionic Matsubara frequency, and \( \omega = 2\pi T \nu (\nu \text{ integer}) \) a bosonic Matsubara frequency. Using

\[ G_{aa}(\mathbf{r}, \mathbf{r}', \omega) = \sum_{\mathbf{k}_{\alpha}, l} \frac{\phi_{\mathbf{k}_{\alpha}, l}(\mathbf{r}) \phi_{\mathbf{k}_{\alpha}, l}(\mathbf{r}')}{i\omega - E_{\mathbf{k}_{\alpha}, l, \sigma}}, \]

we obtain the well-known result

\[ \chi^{(0)}_{\alpha}(\mathbf{q}, \omega) = \sum_n \tilde{I}^2_n(q_x) N_G(q_x - \alpha n G, \omega), \]

where \( \tilde{I}^2_n(q_x) \) is the susceptibility of a one-dimensional system without interaction. In the static limit (\( \omega = 0 \)),

\[ \chi^{(1D)}_{\alpha}(q_x) = \frac{N(0)}{2} \left\{ \ln \left( \frac{2\gamma E_0}{\pi T} \right) + \Psi \left( \frac{1}{2} \right) \right\} - \text{Re} \left\{ \frac{1}{2} \frac{\Psi\left( \frac{1}{2} + \frac{1}{4i\pi T} (q_x - \alpha 2k_F) \right)}{4i\pi T} \right\}. \]

where \( N(0) = 1/\pi v_F b \) is the density of states per spin, \( \Psi \) is the digamma function, and \( \gamma = 1.781 \) the exponential of the Euler constant. \( E_0 \) is an ultraviolet cutoff of the order of the bandwidth. Since \( \chi^{(1D)}_{\alpha}(2k_F) = N(0)/2 \ln(2\gamma E_0/\pi T) \), the bare susceptibility \( \chi^{(0)}_{\alpha} \) has logarithmic divergences at quantized values \( q_x = 2k_F + N G \) (\( N \) integer) of the longitudinal wave vector. The coefficients \( I_n(q_x) \) defined by

\[ I_n(q_x) = \frac{\Gamma(1 + \nu)q_x b^2}{2\pi} \int m e^{-i m q_x b} f_{\mathbf{L}}^{-} f_{\mathbf{L}}^{+} \]

are well known in the QNM.\(^1\) They crucially depend on the detailed structure of the quasi-1D Fermi surface and therefore determine the stability of the metallic phase with respect to the formation of a SDW phase.

**B. RPA susceptibility and phase diagram**

We now consider the total Hamiltonian as given by Eq. (2.3), and introduce the spin susceptibility

\[ \chi_{aa'}(\mathbf{r}, \mathbf{r}', \tau) = \langle T_\tau \psi_{a\uparrow}(\mathbf{r}, \tau) \psi_{a\downarrow}(\mathbf{r}, \tau) \rangle - \langle T_\tau \psi_{a'\uparrow}(\mathbf{r}', \tau) \psi_{a'\downarrow}(\mathbf{r}', \tau) \rangle, \]

In the RPA, \( \chi_{aa'} \) is determined by the integral equation (see Fig. 1)
\[ \chi_{a\alpha'}(\mathbf{r}) = \delta_{a,a'}\chi_{a(0)}(\mathbf{r}) + g_2 \int d^2 r_1 \chi_{a(0)}^{(0)}(\mathbf{r}-\mathbf{r}_1) \chi_{a\alpha'}(\mathbf{r}_1, \mathbf{r}) + g_3 \int d^2 r_1 \chi_{a(0)}^{(0)}(\mathbf{r}-\mathbf{r}_1) e^{i \alpha 4k_F r_1} \chi_{a\alpha'}(\mathbf{r}_1, \mathbf{r}), \]

where we now consider only the static limit \((\omega_p=0)\). In Fourier space, this leads to

\[ \chi_{a\alpha'}(q_x, q_y) = \delta_{a,a'}\delta_{\alpha,\alpha'} \chi_{a(0)}^{(0)}(q_x) + g_2 \chi_{a(0)}^{(0)}(q_x) \chi_{a\alpha'}(q_x, q_y') + g_3 \chi_{a(0)}^{(0)}(q_x) \chi_{a\alpha'}(q_x - \alpha 4k_F, q_y'). \]

(2.13)

We have not written explicitly the dependence on \(q_y\) since the latter is a conserved quantity. Since \(\chi^{(0)}\) logarithmically diverges at \(Q_x^{(N)} = 2k_F + NG\), we consider spin fluctuations only at these wave vectors. Because of umklapp processes, fluctuations at \(Q_x^{(N)}\) are coupled with fluctuations at \(Q_x^{(-N)}\):

\[ \chi_{a\alpha'}(Q_x^{(N)} : Q_x^{(-N)}) = \chi_{a\alpha'}^{(0)}(Q_x^{(N)} : Q_x^{(-N)}) + g_2 \chi_{a(0)}^{(0)}(Q_x^{(N)}) \chi_{a\alpha'}(Q_x^{(N)} : Q_x^{(-N)}) + g_3 \chi_{a(0)}^{(0)}(Q_x^{(N)}) \chi_{a\alpha'}(Q_x^{(N)} : Q_x^{(-N)}). \]

(2.14)

Using \(\chi_{a(0)}^{(0)}(-q_x, q_y) = \chi_{a(0)}^{(0)}(q_x, q_y)\), we obtain

\[ \chi_{a\alpha'}(Q_x^{(N)} : Q_x^{(-N)}) = \chi_{a\alpha'}^{(0)}(Q_x^{(N)} : Q_x^{(-N)}) + g_2 \chi_{a(0)}^{(0)}(Q_x^{(N)}) \chi_{a\alpha'}(Q_x^{(N)} : Q_x^{(-N)}) + g_3 \chi_{a(0)}^{(0)}(Q_x^{(N)}) \chi_{a\alpha'}(Q_x^{(N)} : Q_x^{(-N)}). \]

(2.15)

We have written explicitly the dependence on the transverse wave vector by introducing

\[ Q_N = (Q_x^{(N)} : Q_y) \quad \text{and} \quad Q_{\bar{N}} = (Q_x^{(-N)} : -Q_y). \]

(2.17)

Note that in our notation the wave vector \(Q_N=Q_{\bar{N}}\) has both the signs of \(N\) and \(Q_y\), reversed compared to \(Q_0^{(0)}\). This happens because Umklapp scattering couples \((Q_x^{(N)} : Q_y)\) to \((-Q_x^{(-N)} : Q_y)\), but the latter is equivalent to \((Q_x^{(-N)} : -Q_y)\).

In the presence of umklapp processes, the transition temperature \(T_c^{(N)}\) is determined by the modified Stoner criterion

\[ T_c^{(N)} = \frac{1}{4} \chi_{a(0)}^{(0)}(Q_N) \chi_{a(0)}^{(0)}(Q_{\bar{N}}) \]

which is the condition for vanishing of denominators and divergence of susceptibilities \(\chi_{a\alpha'}\) in Eq. (2.16). Two fluctuation modes diverge simultaneously, which leads to the formation of two SDW’s with wave vectors \(Q_N = (Q_x^{(N)} : Q_y)\) and \(Q_{\bar{N}} = (Q_x^{(-N)} : -Q_y)\) [see Eq. (2.16)]. We label each FISDW phase by the integer \(N\) such that the SDW with wave vector \(Q_N\) has the largest amplitude. This is equivalent to defining \(N\) by the condition \(\chi^{(0)}(Q_N) > \chi^{(0)}(Q_{\bar{N}}) \times (Q_{\bar{N}})\) (Sec. IV).

We will show in Sec. IV that the SDW’s can be either sinusoidal or helicoidal, depending on the value of the angle \(\theta_N (\in [-\pi/4, \pi/4])\) defined by \(\tan(2\theta_N) = 2B/(A_N - A_{\bar{N}})\) and

\[ \gamma = \frac{I_N(Q_N) \tan(\theta_N) - r I_{\bar{N}}(Q_{\bar{N}})}{I_{\bar{N}}(Q_N) - r I_N(Q_{\bar{N}}) \tan(\theta_N)}. \]

(2.20)

where \(r = g_3/g_2\). The figures of this section also show \(1/\gamma = |\tan(\theta_N)|\) which is analogous to \(|\gamma|\) but for the effective mean-field potential acting on the electrons. (\(\gamma\) and \(\gamma\) are precisely defined in section IV.) \(1/\gamma\) and \(\gamma\) increase with \(|\theta_N|\). At the transition between the sinusoidal and helicoidal phases \(|\gamma| - |1/\gamma| = 0.518\).

In the absence of umklapp processes, Eq. (2.18) yields the usual Stoner criterion \(1 - g_2 \chi^{(0)}(Q_N) = 0\) for the formation
of a SDW at wave vector $Q_y=(Q_y^{(N)}, Q_y^{(N)})$. The quantized longitudinal wave vector $Q_y^{(N)}=2k_F+NG$ and the transverse wave vector $Q_y$ are chosen to maximize the transition temperature $T_c^{(N)}$ at a given magnetic field. Except when $N=0$, $Q_y$ is incommensurate: $Q_y \neq \pi/b$. The SDW is sinusoidal ($\bar{g}_y=0$ for $g_3=0$), and the quantum Hall conductivity in the FISDW is determined by the integer $N$: $\sigma_{xy}=-2Ne^2/h$. As the magnetic field increases, the value of $N$ changes, which leads to a cascade of FISDW phases separated by first-order transitions. In the simplest version of the QNM, where $t_{3b}=t_{4b}=\cdots=0$, the phases of the cascade are labeled by $N=-5,4,3,2,1,0$ as the magnetic field increases. The integer $N$ is positive provided $t_{2b}>0$, i.e., $\text{sgn}(N)=\text{sgn}(t_{2b})$. (For $t_{2b}<0$, one would obtain a similar sequence but with negative values of $N$.)

We study the phase diagram in the presence of umklapp scattering numerically (see Figs. 2–6). The calculations are done for $t_b=300$ K, $t_{2b}=20$ K, $t_{4b}=0$ K, and $E_0=2000$ K. $\bar{g}_2+\bar{g}_3=2\ln(2\gamma E_0/\pi T_c^{(N)})$ is held fixed where $T_c^{(N)}=12$ K is the transition temperature for an infinite magnetic field, and $\bar{g}_y=N(0)g_y, (i=2,3)$ are dimensionless coupling constants. Since the values of $r$ and $t_{4b}$ are not precisely known in Bechgaard salts, we calculate the phase diagram as a function of these parameters. (In Bechgaard salts, $t_{4b}$ is expected to be a very small energy scale, of order 1 K or even less.\(^\text{16}\)) $\bar{g}_2$ and $\bar{g}_3$ are such that we are in the weak-coupling limit: $\bar{g}_3<\bar{g}_2<0.4$.

For $r=0$ and $t_{4b}=0.75$ K, we obtain the sequence $N=-5,4,3,2,1,0$ in agreement with what has been found for $t_{4b}=0$ (i.e., a small value of $t_{4b}$ does not change the phase diagram when $r=0$).\(^\text{1}\) The transverse wave vector $Q_y$ varies approximately linearly with the field within each phase, and is incommensurate ($Q_y \neq \pi/b$) except in the phase $N=0$ (Fig. 2).

A very small $g_3$ does not change the phase diagram qualitatively compared to the case $g_3=0$. Now the main SDW at the wave vector $Q_y$ coexists with a weak SDW at the wave vector $Q_N$. In general, the value of $Q_N$ that maximizes $\chi^{(0)}(Q_N)$ does not maximize $\chi^{(0)}(Q_y)$, so $\chi^{(0)}(Q_N) \ll \chi^{(0)}(Q_y)$. As a result, the SDW amplitude at the wave vector $Q_N$ is very small, and the polarizations of the SDW’s are linear. The values of $N$ follow the usual positive sequence $N=-5,4,3,2,1,0$ as the magnetic field increases.

A larger value of $g_3$ increases the coupling between the two SDW’s. This leads to a strong decrease of the critical temperature or even the disappearance of the SDW’s. However, for even $N$, there exists a critical value of $g_3$ above which the system prefers to choose the transversely commensurate wave vector $Q_y=\pi/b$ for both SDW’s. The reason is that, for even $N$ (as opposed to odd $N$), $Q_y=\pi/b$ corresponds to a local maximum of the susceptibilities $\chi^{(0)}(Q_y^{(N)}, \pi/b)=\chi^{(0)}(Q_y^{(N)}, \pi/b)$. The two susceptibilities are strictly equal at $t_{4b}=0$, but when $t_{4b}>0$, $\chi^{(0)}(Q_y^{(N)}, \pi/b)>\chi^{(0)}(Q_y^{(N)}, \pi/b)$ (this result also holds for $t_{4b} \neq 0$ since $\chi^{(0)}(Q_y^{(N)}, \pi/b)$ is independent of $t_{4b}$).\(^\text{16}\) This yields a negative Hall plateau, provided the SDW’s are sinusoidal. Thus, for $r=0.025$ ($\bar{g}_2=0.37$ and $\bar{g}_3=0.01$) and $t_{4b}=0.75$ K, we find the sequence $N=-5,4,3,2,1,0$ (Fig. 3). A negative commensurate phase with $N=-2$ and $Q_y=\pi/b$ appears in the cascade. All the phases are sinusoidal, so the Hall effect is quantized ($\sigma_{xy}=-2Ne^2/h$). For $r=0.025$ and $t_{4b}=0.75$ K, we obtain only positive integers: $N=-5,4,3,2,1,0$. However, the phase $N=2$ has split into two subphases: for large enough field, the transverse wave vector $Q_y$ differs from $\pi/b$ and varies linearly with the field; for a weaker field, the phase is commensurate ($Q_y=\pi/b$). All the phases are sinusoidal $[\sin^2(2\theta_y)<2/3]$ so that the Hall effect is quantized.

Figure 3 shows that both SDW’s have comparable amplitudes in the negative phases: $|\gamma_y|, |\gamma_N|=0.3$. This results from the property $\chi^{(0)}(Q_y^{(N)}, \pi/b)=\chi^{(0)}(Q_y^{(N)}, \pi/b)$. On the contrary, the amplitude of the SDW with wave vector $Q_N$ remains very small in the positive phases. Note that it is $\gamma$ which is actually vanishingly small, $|\gamma|$ being of the order of $r$ (see Sec. IV A for a further discussion).

The strength of umklapp scattering is very sensitive to pressure. Indeed, hydrostatic pressure reduces the dimerization gap and diminishes $g_3$. Therefore, we conclude that sign reversals of the QHE can be induced by varying pressure. In our simplified model, this effect requires $t_{4b}>0$. Our results provide a new explanation of the sign reversals of the QHE which have long been observed in quasi-1D organic conductors.\(^\text{10–14}\) In particular, Balicas et al. have recently shown unambiguously the existence of the phase $N=-2$ in (TMTSF)$_2$PF$_6$ at a pressure of 8.3 kbar by observing a sign reversal of the QHE with a well-defined Hall plateau corresponding to $N=-2$.\(^\text{14}\) (These results required a conditioning procedure in which current pulses depin the FISDW from lattice defects and tend to reduce hysteresis.) The observed FISDW cascade corresponds to $N=-4,3,2,1,0$. When the pressure is increased to 9 kbar (which decreases the umklapp scattering strength), the phase $N=-2$ disappears and the usual sequence $N=-4,3,2,1,0$ is obtained.

If the value of $t_{4b}$ is reduced, the phase $N=-2$ becomes helicoidal. This is shown in Fig. 4 obtained for $r=0.03$ and...
tain a main SDW, which coexists with another SDW with a wave vector $\mathbf{Q}_x = (0, 0, Q_x)$ of the SDW with wave vector $\mathbf{Q}_y = (Q_y, 0, 0)$ and $\mathbf{Q}_z = (0, Q_z, 0)$, numerical calculations. For instance, for $r = 0.025$ and $t_{4b} = 0.75$ K, the bottom picture shows $\sin^2(2\theta_0)$ (solid line), $|\gamma|$ (dashed line), and $|\gamma|$ (dotted line). $\sin^2(2\theta_0)$ determines the polarization of the SDW’s and $|\gamma|$ give the ratio of the amplitudes of the two SDW’s (see text for a precise definition). (These quantities are not shown in the last phase of the cascade ($N = 0$, $\mathbf{Q}_x = (\pi/b)$) which contains a single linearly polarized SDW.) A negative phase ($N = -2$) appears in the cascade. $\mathbf{Q}_x = \pi/b$ in that phase, and the two SDW’s have comparable amplitudes: $|\gamma|, |\gamma| \sim 0.3$. All the phases are sinusoidal [since $\sin^2(2\theta_0) < 2/3$] and the Hall effect is quantized: $\sigma_{xy} = -2Ne^2/3h$.

$t_{4b} = 0.3$ K. (When $t_{4b} = 0.3$ K, the phase $N = -2$ appears for stronger umklapp scattering. This is the reason why we show the phase diagram for $r = 0.03$ and not $r = 0.025$.) In the helicoidal phase, $|\gamma|, |\gamma| \sim 0.5$. For $t_{4b} = 0$, there is a degeneracy between $N$ and $-N$ at $\mathbf{Q}_x = \pi/b$: $\chi^{(0)}(\mathbf{Q}_x, \pi/b) = \chi^{(0)}(\mathbf{Q}_x, \pi/b)$, $I_N(\pi/b) = I_N(\pi/b)$ and $A_N = A_N$. This yields $|\gamma|, |\gamma| = 1$ and $\theta_N = \pi/4$; the waves are helicoidal. A finite $t_{4b}$ lifts this degeneracy, so that $A_N \neq A_N$ and in turn $\sin^2(2\theta_0) < 1$. Thus, the stability of the helicoidal phases is strongly related to the degeneracy between $N$ and $-N$ occurring for $\mathbf{Q}_x = \pi/b$. In our model, this degeneracy is entirely controlled by $t_{4b}$. It is not affected by $t_{3b}$, which is the reason why we have chosen $t_{3b} = 0$ in the numerical calculations.

If, on the other hand, the value of $t_{4b}$ is increased, the ratio of the amplitudes of the two SDW’s decreases. For instance, for $r = 0.025$ and $t_{4b} = 1.5$ K, we find $|\gamma|, |\gamma| \sim 0.15$. Thus, for large $t_{4b}$ (i.e., $t_{4b} \geq 1.5$ K), the amplitude of the SDW with wave vector $\mathbf{Q}_x$ becomes very small. There is then no real difference between a positive and a negative phase (except for the sign of the QHE) insofar as both contain a main SDW, which coexists with another SDW with a very small amplitude.

If $r$ is increased to 0.06 (with $t_{4b} = 0.75$ K), a second negative phase ($N = -4$) appears, and the cascade becomes $N = -8, 7, -4, 6, 5, 4, -2, 2, 1, 0$ (Fig. 5). Note that $N = -2$ and $N = -4$ are the two negative phases most easily observed in experiments. The phase $N = -2$ has split into two subphases: one is helicoidal [sin^2(2\theta_0) > 2/3], one is sinusoidal [sin^2(2\theta_0) < 2/3]. Thus, increasing the strength of umklapp processes makes the negative phase $N = -2$ helicoidal.

In order to observe the helicoidal phase experimentally, it would be desirable to stabilize the negative phase $N = -2$ at the lowest possible pressure (which corresponds to the strongest $g_3$). In (TMTSF)$_2$PF$_6$, the pressure has to be larger than 6 kbar, since below this pressure the FISDW cascade disappears. In the experiment reported in Ref. 14, where the...
EFFECT OF UMKLAPP SCATTERING ON THE...

phase \( N = -2 \) has been observed at 8.3 kbar, the pressure could be reduced only by about 2 kbar. Nevertheless, because \( g_3 \) is very sensitive to pressure, such a pressure reduction could induce a significant increase of the umklapp scattering strength. (TMTSF)\(_2\)ReO\(_4\), where sign reversals of the QHE have been observed under pressure,\(^{23}\) could also be a good candidate for the observation of helicoidal phases. In (TMTSF)\(_2\)ClO\(_4\), sign reversals of the QHE have been observed at ambient pressure,\(^{1,10}\) so that it is not possible to increase \( g_3 \) by decreasing pressure.

When \( r \) is further increased, only phases with negative even \( N \) survive. This leads to the sequence \( N = \cdots -8, -6, -4, -2 \) for \( t_{ab} = 0.75 \) K apart from some reentrances of the phase \( N = 0 \) within the cascade to be discussed below. For \( t_{ab} = 0.75 \) K, we obtain the sequence \( N = \cdots -8, 6, 4, 2, 0 \). Moreover, all the phases \( N \neq 0 \) are commensurate \((Q_y = \pi/b)\). This is shown in Fig. 6 obtained for \( r = 0.2 \), i.e., \( \tilde{g}_2 = 0.32 \) and \( \tilde{g}_3 = 0.06 \).

The phase \( N = 0 \) is somehow special since \( \chi_+^{(0)}(Q_\alpha) = \chi_+^{(0)}(Q_\beta) \) in that case. As a result, the transition temperature \( T_c^{(0)} \) is determined by \( 1 - (g_2 + g_3)\chi_+^{(0)}(Q_0) = 0 \) and does not depend on the ratio \( r = g_3/g_2 \). This should be contrasted with the transition temperature \( T_c^{(N)}(N \neq 0) \) which decreases with \( r \) [except when \( Q_y = \pi/b \) and \( \chi_+^{(0)}(Q_y^{(N)}, \pi/b) = \chi_+^{(0)}(Q_x^{(N)}, \pi/b) \)]. This explains why, when \( r \) increases, some reentrances of the phase \( N = 0 \) are observed within the cascade. Notice that the latter phases are not commensurate \((Q_y \neq \pi/b)\) contrary to the last phase \( (N = 0, Q_y = \pi/b) \) of the cascade. The reentrant phases \( N = 0 \) are always helicoidal (independently of the structure of the Fermi surface), but the last phase \( N = 0, Q_y = \pi/b \) of the cascade is sinusoidal (Sec. IV).

C. Effect of 1D fluctuations

Our numerical results show that a very small value of the umklapp scattering amplitude is sufficient to explain the phase diagram of Bechgaard salts. In fact, the order of magnitude of \( g_3 \) which is required to stabilize negative phases strongly depends on the choice of the ultraviolet cutoff \( E_0 \).

Within a mean-field picture, \( E_0 \) is a large energy, of the order of the electron bandwidth. It has been argued that because of 1D fluctuations, the appropriate cutoff to be used in the QNM is not the bandwidth but the dimensional crossover temperature \( T_{c1} \approx E_0 \).\(^{24}\) (Above \( T_{c1} \), the behavior of the system is essentially 1D, so that the interference between particle-particle and particle-hole channels invalidate the mean-field (or ladder) approximation.) A stronger value of \( g_3 \) is then required to stabilize negative phases. This is in agreement with the suggestion of Behnia et al. that the effective low-temperature value of \( g_3 \) in a magnetic field is significantly enhanced by 1D high-energy scales.\(^{25}\) This point of view is supported by NMR measurements and a large magnetoresistance, which shows an activated behavior becoming more and more pronounced as the field increases.\(^{25}\)

III. ORDER PARAMETERS: HELICOIDAL VS SINUSOIDAL WAVES

The divergence of the susceptibilities \( \chi_{aa^*} \) (Sec. II) indicates that the FISDW phases are characterized by the order parameters

\[
\Delta_{aa^*}(r) = \langle \psi_{aa^*}^{\dagger}(r) \psi_{aa^*}(r) \rangle = \sum_{p = \pm} \Delta_{aa^*}^{(pN)} \epsilon^{-i p Q_y r}. \tag{3.1}
\]

The two wave vectors \( Q_{pN}, p = \pm 1 \), are given by Eq. (2.17). \( Q_x^{(pN)} = 2 k_F + p N G \) and \( Q_y^{(pN)} = -Q_y^{(N)} \). The complex numbers \( \Delta_{aa^*}^{(pN)} \) are the order parameters of the FISDW phase. \( \Delta_{aa^*}(r) = \Delta_{aa^*}^{(pN)}(r) \) implies \( \Delta_{aa^*}^{(pN)} = \Delta_{aa^*}^{(N)} \). Among the eight order parameters \( \Delta_{aa^*}^{(pN)} \), only four are therefore independent and sufficient to characterize the SDW phase. Note that for \( N = 0 \), one should distinguish in general between the phases \( N = 0 \) and \( \bar{N} \). In this case, there are two SDW’s with wave vectors \( (2 k_F, Q_y^{(0)}) \) and \( (2 k_F, Q_y^{(0)}) \) with \( Q_y^{(0)} = -Q_y^{(0)} \). For \( Q_y^{(0)} = 0, \pi/b, \) the two SDW’s are different so that both \( \Delta_{aa}^{(0)} \) and \( \Delta_{aa}^{(\pi/b)} \) are needed. When \( Q_y^{(0)} = 0, \pi/b, \) the two SDW’s are identical, and only one order parameter (for instance \( \Delta_{aa}^{(0)} \)) is sufficient.

Now we discuss how the polarization of the wave affects the order parameters \( \Delta_{aa^*} \). For simplicity, we consider only one wave vector \( Q \) and denote the four different order parameters by \( \Delta_{aa} \) (among which only two are independent since \( \Delta_{aa} = \Delta_{aa}^{(\pi/b)} \)). For a SDW polarized perpendicularly to
the magnetic field, the expectation value of the spin-density operator $\mathbf{S}(\mathbf{r})$ can be written as

$$
\langle S_z(\mathbf{r}) \rangle = \sum_{a,a',\sigma} \langle \psi_{a\sigma}(\mathbf{r}) \mathbf{T}_{a,a'} \psi_{a'\sigma}(\mathbf{r}) \rangle = m_z \cos(\mathbf{Q} \cdot \mathbf{r} + \theta_1),
$$

$$
\langle S_y(\mathbf{r}) \rangle = \sum_{a,a',\sigma} \langle \psi_{a\sigma}(\mathbf{r}) \mathbf{T}_{a,a'} \psi_{a'\sigma}(\mathbf{r}) \rangle = m_y \cos(\mathbf{Q} \cdot \mathbf{r} + \theta_2),
$$

where $\mathbf{T}^{(a)}$ and $\mathbf{T}^{(y)}$ are Pauli matrices. $\theta_1 = \theta_2$ corresponds to a sinusoidal wave, while $\theta_1 = \theta_2 \pm \pi/2$ and $m_z = m_y$ corresponds to a helicoidal wave. $(\mathbf{S}(\mathbf{r}))$ can be expressed in terms of the order parameters (3.1):

$$
\langle S^\alpha(\mathbf{r}) \rangle = \langle S_\alpha(\mathbf{r}) \rangle + i \langle S_\beta(\mathbf{r}) \rangle
$$

$$
= \sum_a \langle \psi_{a\sigma}(\mathbf{r}) \psi_{a\sigma}(\mathbf{r}) \rangle = \Delta_{a\alpha}(\mathbf{r}).
$$

(3.3)

Comparing this expression with Eqs. (3.2), we find

$$
\Delta_{+1} = \frac{1}{2} (m_x e^{-i\theta_1} + im_y e^{-i\theta_2}),
$$

$$
\Delta_{-1} = \frac{1}{2} (m_x e^{i\theta_1} + im_y e^{i\theta_2}).
$$

(3.4)

For a sinusoidal wave $|\Delta_{+1}| = |\Delta_{-1}|$. For a helicoidal wave $\Delta_{+1} \neq 0$ and $\Delta_{-1} = 0$ (or the symmetric solution $\Delta_{-1} \neq 0$ and $\Delta_{+1} = 0$). The inverse is also true: $|\Delta_{+1}| = |\Delta_{-1}|$ implies that the wave is sinusoidal, while $\Delta_{+1} \neq 0$ and $\Delta_{-1} = 0$ implies that the wave is helicoidal.

**IV. POLARIZATION OF THE PHASE N**

In this section we derive the Ginzburg-Landau expansion of the free energy as a function of the order parameters $\Delta^{(pN)}$. The minimum of the free energy determines the polarization (linear or circular) of the SDW's.

The mean-field (or Hartree-Fock) Hamiltonian is given by

$$
\mathcal{H}_{\text{MF}} = \mathcal{H}_0 - \sum_{a,a'} \int d^2 r \tilde{\Delta}_{a\alpha}(\mathbf{r}) \psi_{a\alpha}^\dagger(\mathbf{r}) \psi_{a\alpha}(\mathbf{r})
$$

$$
+ \sum_{a} \int d^2 r \tilde{\Delta}_{a\alpha}(\mathbf{r}) \Delta_{a\alpha}(\mathbf{r}),
$$

(4.1)

where we have introduced

$$
\tilde{\Delta}_{a\alpha}(\mathbf{r}) = g_2 \Delta_{a\alpha}(\mathbf{r}) + g_3 e^{-i\alpha k_F} \Delta_{a\alpha}(\mathbf{r}).
$$

(4.2)

$\Delta_{a\alpha}(\mathbf{r})$ is given by Eq. (3.1). For $g_3 \neq 0$, the mean-field potential $\tilde{\Delta}_{a\alpha}(\mathbf{r})$ acting on the electrons is a linear combination of the order parameters $\Delta_{a\alpha}(\mathbf{r})$.

Calculating the free energy (per surface unit) of the phase $N$ to the fourth order in the order parameters, we obtain $F_N = F_N^{(2)} + F_N^{(4)}$ with

$$
F_N^{(2)} = \sum_a \int \frac{d^2 r}{L_x L_y} \Delta_{a\alpha}(\mathbf{r}) \Delta_{a\alpha}(\mathbf{r})
$$

$$
+ \frac{T}{L_x L_y} \sum_{a,a',\omega \epsilon w_1, w_2} \int d^2 r_1 d^2 r_2 \Delta_{a\alpha}(\mathbf{r}_1) \Delta_{a\alpha}(\mathbf{r}_2)
$$

$$
\times G_{a\alpha}(\mathbf{r}_1, \mathbf{r}_2, \omega) G_{a\alpha}^*(\mathbf{r}_2, \mathbf{r}_1, \omega),
$$

(4.3)

$$
F_N^{(4)} = \frac{T}{2L_x L_y} \sum_{a,a',\omega \epsilon w_1, w_2, \epsilon w_3, w_4} \int d^2 r_1 d^2 r_2 d^2 r_3 d^2 r_4 \Delta_{a\alpha}(\mathbf{r}_1) \Delta_{a\alpha}(\mathbf{r}_2)
$$

$$
\times \Delta_{a\alpha}(\mathbf{r}_3) \Delta_{a\alpha}(\mathbf{r}_4) G_{a\alpha}(\mathbf{r}_1, \mathbf{r}_2, \omega) G_{a\alpha}^*(\mathbf{r}_2, \mathbf{r}_1, \omega)
$$

$$
\times G_{a\alpha}(\mathbf{r}_3, \mathbf{r}_4, \omega) G_{a\alpha}^*(\mathbf{r}_4, \mathbf{r}_3, \omega).
$$

$G_{a\alpha}$ is the single-particle Green’s function in the metallic phase [see Eq. (2.8)]. Introducing the electron-hole pairing amplitude [we use the notation $w_i = (k_i, \ell_i)$ for the indices of the functions $\phi_{\ell_i, k_i}^a$ (Eq. (2.4))]

$$
\tilde{\Delta}_{a\alpha}(w_1, w_2) = \int d^2 r \phi_{\ell_1, k_1}^a(\mathbf{r}) \phi_{\ell_2, k_2}^a(\mathbf{r}) \Delta_{a\alpha}(\mathbf{r}) = \tilde{\Delta}_{a\alpha}^{\epsilon}(w_1, w_2),
$$

(4.4)

we write the free energy as

$$
F_N^{(2)} = \sum_{a,a'} \left[ A_{a\alpha} \right] \tilde{\Delta}_{a\alpha}^{\epsilon}(w_1, w_2)
$$

$$
+ B \tilde{\Delta}_{a\alpha}^{\epsilon}(w_1, w_2) + c.c.,
$$

(4.5)

$$
F_N^{(4)} = \frac{T}{2L_x L_y} \sum_{a,a',\omega \epsilon w_1, w_2, \epsilon w_3, w_4} \Delta_{a\alpha}(w_1, w_2) \Delta_{a\alpha}(w_3, w_4) \Delta_{a\alpha}(w_4, w_2) \Delta_{a\alpha}(w_2, w_1)
$$

$$
\times \left( i \omega - \epsilon_{w_1} \right) \left( i \omega - \epsilon_{w_2} \right) \left( i \omega - \epsilon_{w_3} \right) \left( i \omega - \epsilon_{w_4} \right).
$$

(4.6)

The pairing amplitudes are given by (Appendix A)

$$
\tilde{\Delta}_{a\alpha}(w_1, w_2) = \sum_{p = \pm} \delta_{k_2, k_1 + aQ^N} (g_2 \Delta^{(pN)}_{a\alpha} + g_3 \Delta^{(pN)}_{a\alpha})
$$

$$
\times e^{-i\alpha k_F} (l_1 + l_2)^2 I_{a\alpha}(l_1 - l_2)(Q^N)_{l_1, l_2, w_1, w_2}.
$$

(4.7)

This leads to

$$
F_N^{(2)} = \sum_{a,a'} \left[ A_{a\alpha} \right] \tilde{\Delta}_{a\alpha}^{\epsilon}(w_1, w_2) + B \tilde{\Delta}_{a\alpha}^{\epsilon}(w_1, w_2) + \delta F_0^{(2)},
$$

(4.8)

$$
\delta F_0^{(2)} = \delta F_0^{(2)} \left[ \sum_n \delta Q_n^{(0)b,a} \right] \sum_{a,a'} A_{a\alpha} \left( \tilde{\Delta}_{a\alpha}^{(0)} \tilde{\Delta}_{a\alpha}^{(0)*} + c.c. \right)
$$

$$
+ B \left( \tilde{\Delta}_{a\alpha}^{(0)} \tilde{\Delta}_{a\alpha}^{(0)*} + \tilde{\Delta}_{a\alpha}^{(0)\dagger} \tilde{\Delta}_{a\alpha}^{(0)\dagger*} \right).
$$

This leads to
$A_{\pi N}$ and $B$ are defined by Eq. (2.19). We have introduced the new order parameters $\tilde{\Delta}_{a\pi}^{(pN)}$ related to $\Delta_{a\pi}^{(pN)}$ by

$$\tilde{\Delta}_{a\pi}^{(pN)} = I_{pN} (g_2^{(pN)} g_3^{(pN)} + g_3^{(pN)} g_2^{(pN)}) = \Delta_{a\pi}^{(pN)}$$

$$\tilde{\Delta}_{a\pi}^{(pN)} = \frac{g_2 I_{pN} \tilde{\Delta}_{a\pi}^{(pN)} - g_3 I_{pN} \tilde{\Delta}_{a\pi}^{(pN)}}{(g_2^2 - g_3^2) I_{pN} \tilde{\Delta}_{a\pi}^{(pN)}}$$

with $I_{pN} = I_{pN} (Q^{(pN)}_y)$.

A commonly used approximation in the QNM is the quantum limit approximation (QLA) valid when $\omega_c \gg T$. It consists in retaining only the most singular (electron-hole) pairing channels that have the logarithmic singularity $\sim \ln(2\gamma E_0/\pi T)$. This singularity results from pairings between electron and hole states of the same energy. Therefore, in the QLA, $\tilde{\Delta}_{a\pi} (w_1, w_2)$ is nonzero only if $\epsilon_{w_1\pi}^{a} = -\epsilon_{w_2\pi}^{a}$. This leads to

$$\tilde{\Delta}_{a\pi} (w_1, w_2) |_{\text{QLA}} = \sum_{p = \pm} \delta (w_1, w_2 + a Q^{(pN)}_y \delta (w_2, w_1 - a p N)$$

$$\times e^{- (a Q^{(pN)}_y) (2 w_1 - a p N) / Q_{y}^{(pN)} \bar{l}}$$

(4.10)

$$F_N^{(4)} = \frac{K}{2} \sum_{\alpha \beta} \sum_{p_1, p_2, p_3, p_4} \tilde{\Delta}_{\alpha \pi} (p_1 N) \tilde{\Delta}_{\beta \pi} (p_2 N)^* \tilde{\Delta}_{\alpha \pi} (p_3 N) \tilde{\Delta}_{\beta \pi} (p_4 N)^* \exp \left[ i N (b / 2) \left( p_1 Q^{(pN)}_y - (2 p_1 - p_2) Q^{(pN)}_y + (2 p_1 - 2 p_2 + p_3) Q^{(pN)}_y - p_4 Q^{(pN)}_y \right) \right] \delta (p_1 - p_2 - p_3 - p_4) \sum_{\beta} \delta (Q^{(pN)}_y - Q^{(pN)}_y - Q^{(pN)}_y - Q^{(pN)}_y , n 2 \pi / b)$$

(4.12)

where $K = 7 \zeta (3) N (0) / (16 \pi^2 T^2)$ and $\zeta (3) = 1.20$. A somewhat lengthy calculation (see Appendix B) leads to

$$F_N^{(4)} = \frac{K}{2} \sum_{\alpha \beta} \sum_{p, a} \left| \tilde{\Delta}_{\alpha \pi} (p N) \right|^4 + 2 K \sum_{\alpha \beta} \left| \tilde{\Delta}_{\alpha \pi} (p N) \tilde{\Delta}_{\alpha \pi} (p N)^* \right|^2 + \delta F_0^{(4)}$$

(4.13)

$$\delta F_0^{(4)} = \delta \left( \sum_{\alpha} \sum_{\beta} \delta (Q^{(pN)}_y - n \pi / b) \left[ \sum_{\alpha \beta} \left( \tilde{\Delta}_{\alpha \pi} (p N) \tilde{\Delta}_{\alpha \pi} (p N)^* + \frac{1}{2} \left( \tilde{\Delta}_{\alpha \pi} (p N) \tilde{\Delta}_{\alpha \pi} (p N)^* \right)^2 + \cdots \right] \right)$$

Equations (4.8) and (4.13) show that the case $N = 0$ and $Q^{(pN)}_y = 0, \pi / b$ is special, since in that case one cannot distinguish between $\tilde{\Delta}_{a\pi}^{(0)}$ and $\tilde{\Delta}_{a\pi}^{(0)}$. In practice, the case $Q^{(0)}_y = 0$ never occurs (see Sec. II) so that we shall not consider it any more.

A. Phases $N \neq 0$, or $N = 0$ and $Q^{(0)}_y \neq \pi / b$

We first consider the cases $N \neq 0$, and $N = 0$ with $Q^{(0)}_y \neq \pi / b$. The latter corresponds to the reentrant phases $N = 0$ within the cascade (see Sec. II). The quadratic part of the free energy (4.8) is not diagonal in the order parameters

$$\chi_+^{(0)} (Q^{(pN)}_y) \left|_{\text{QLA}} = F_N^{(2)} - \frac{N (0)}{2} \ln \left( \frac{2 \gamma E_0}{\pi T} \right) \right.$$
\[
\lambda_1^{(N)} = A_N \cos^2(\vartheta_N) + A_N \sin^2(\vartheta_N) + B \sin(2\vartheta_N)
\]
\[
= \frac{A_N + A_N}{2} + \frac{1}{2} \text{sgn}(A_N - A_N)[(A_N - A_N)^2 + 4B^2]^{1/2},
\]
\[
\lambda_2^{(N)} = A_N \sin^2(\vartheta_N) + A_N \cos^2(\vartheta_N) - B \sin(2\vartheta_N)
\]
\[
= \frac{A_N + A_N}{2} - \frac{1}{2} \text{sgn}(A_N - A_N)[(A_N - A_N)^2 + 4B^2]^{1/2}.
\]  

The transition temperature \(T^{(N)}\) is determined by \(\min(\lambda_1^{(N)}, \lambda_2^{(N)}) = 0\). In this section, the sign of \(N\) has not been specified yet, since both phases \(N\) and \(-N\) correspond to a phase with two SDW’s at wave vectors \((Q_x^{(N)}, Q_y^{(N)})\) and \((Q_x^{(-N)}, Q_y^{(-N)})\). In the following, we fix the sign of \(N\) by the condition \(\chi_{+}^{(0)}(Q_N) \geq \chi_{+}^{(0)}(Q_{-N})\) (i.e., in the absence of umklapp processes, the phase \(N\) would be more stable than the phase \(-N\)). Then we have \(0 < A_N < A_N^*\) and \(0 < \lambda_1^{(N)} < \lambda_2^{(N)}\) for \(T > T^{(N)}\) (assuming \(0 < g_3 < g_2\)). The transition temperature \(T^{(N)}\) is determined by \(\lambda_1^{(N)} = 0\), i.e., \(A_N = A_N^*\). Using Eqs. (2.19), we recover the result (2.18) obtained from the RPA calculation of the susceptibility.

Since \(\lambda_2^{(N)} > 0\) for \(T > T^{(N)}\), we can put \(u_{a}^{(N)} = 0\) in the expansion of the free energy. This leads to
\[
F_N = \lambda_1^{(N)} \sum_a |u_a^{(N)}|^2 + \frac{K}{2} [\cos^4(\vartheta_a) + \sin^4(\vartheta_a)]
\]
\[
\times \sum_a |u_a^{(N)}|^4 + K \sin^2(2\vartheta_a) |u_a^{(N)}|^2.
\]  

The minimum of the free energy is determined by
\[
\frac{\partial F_N}{\partial u_a^{(N)*}} = u_a^{(N)}[\lambda_1^{(N)} + K\cos^4(\vartheta_a) + \sin^4(\vartheta_a)]|u_a^{(N)}|^2
\]
\[
+ K \sin^2(2\vartheta_a) |u_a^{(N)}|^2 = 0.
\]  

For \(\lambda_1^{(N)} < 0\) (i.e., \(T < T^{(N)}\), there are two solutions corresponding to a SDW phase:

(i) \(|u_a^{(N)}|^2 = |u_a^{(0)}|^2 \neq 0\). Using \(v_a = 0\), we find \(|\Delta_a^{(N)}|^2 = |\Delta_a^{(0)}|^2\), \(|\Delta_a^{(N)}| = |\Delta_a^{(0)}|\), and also \(|\Delta_a^{(N)}| = |\Delta_a^{(0)}|, \quad |\Delta_a^{(N)}| = |\Delta_a^{(0)}|\). From the results of Sec. III, we conclude that the two SDW’s are linearly polarized.

(ii) \(u_a^{(N)} \neq 0\) and \(u_a^{(N)} = 0\) (or the symmetric solution: \(u_a^{(N)} \neq 0\) and \(u_a^{(N)} = 0\)). \(v_a = 0\) then implies \(\Delta_a^{(N)} = \Delta_a^{(0)} = 0\), and \(\Delta_a^{(N)} = \Delta_a^{(0)} = 0\). This corresponds to two helicoidal SDWs of opposite chiralities.

For the sinusoidal waves [solution (i)], we find
\[
|u_a^{(N)}|^2 = -\frac{\lambda_1^{(N)}}{K[1 + (1/2)\sin^2(2\vartheta_a)]},
\]
\[
F_N = -\frac{\lambda_1^{(N)}^2}{K[1 + (1/2)\sin^2(2\vartheta_a)]}.
\]  

while for the helicoidal waves [solution (ii)], we have
\[
|u_a^{(N)}|^2 = -\frac{\lambda_1^{(N)}}{K[1 + (1/2)\sin^2(2\vartheta_a)]}, \quad u_+^{(N)} = 0,
\]
\[
F_N = -\frac{\lambda_1^{(N)}^2}{2K[1 + (1/2)\sin^2(2\vartheta_a)]}.
\]  

Comparing Eqs. (4.21) and (4.23), we conclude that the helicoidal phase is more stable than the sinusoidal phase when \(\sin^2(2\vartheta_a) < 2/3\), i.e., when \(\sqrt{2} |B| > |A_N - A_N^*|\). When \(\sin^2(2\vartheta_a) < 2/3\), the minimum of \(F_N\) for \(\lambda_1^{(N)} < 0\) corresponds to \(u_+^{(N)} = |u_+^{(N)}|\). When \(\sin^2(2\vartheta_a) > 2/3\), there are two minima located on the lines \(u_+^{(N)} = 0\) and \(u_-^{(N)} = 0\).

In the absence of umklapp processes \((g_3 = 0)\), \(\Delta_a^N = 0\) and the SDW’s are sinusoidal. For values of \(g_3\) such that \(Q_+^{(N)} = \pi/b\), the polarization of the waves depends on the details of the Fermi surface. In our model, it is determined by \(t_{4b}\) (see the numerical calculation of Sec. II).

The results obtained in this section are very simple when \(N = 0\). Since \(\chi_{+}^{(0)}(Q_N) = \chi_{+}^{(0)}(Q_{-N})\) for \(N = 0\) (the susceptibility does not change when \(Q_{+} \rightarrow -Q_{+}\)). \(A_N = A_N^*\) and \(\vartheta_0 = \pi/4\). The phase \(N = 0\) (with \(Q_+ \neq \pi/b\)) is therefore always helicoidal. This result does not hold when \(Q_+ = \pi/b\) (see Sec. IV B).

Using \(v_a^{(N)} = 0\), we obtain the ratio of the amplitudes of the two SDW’s:
\[
\gamma = \frac{\Delta_a^{(N)}}{\Delta_a^{(0)}} = \tan(\vartheta_a),
\]
\[
\gamma = \frac{\Delta_a^{(N)}}{\Delta_a^{(0)}} = \frac{\gamma I_N - r I_\delta}{I_N - r \gamma I_\delta}.
\]  

Since \(\vartheta_a \in [-\pi/4, \pi/4]\), \(\gamma, |\gamma| \leq 1\). The SDW with wave vector \(Q_N\) has the largest amplitude. This simply results from the fact that we have chosen \(N\) such that \(\chi_{+}^{(0)}(Q_N) \geq \chi_{+}^{(0)}(Q_{-N})\). The transition from the sinusoidal phase to the helicoidal phase occurs when \(\sin^2(2\vartheta_a) = 2/3\), i.e., when \(\gamma = 0.518\).

Note that in the positive phases, it is \(\gamma\) and not \(\gamma\) which is vanishingly small. When \(\chi_{+}^{(N)}(Q_N) \leq \chi_{+}^{(N)}(Q_{-N})\), the minimum of the free energy corresponds to \(\Delta_a^{(N)} = 0\) (and not \(\Delta_a^{(0)} = 0\)), since it is the potential \(\Delta_a^{(N)}\) (and not \(\Delta_a^{(0)}\)) that couples to the electrons [see Eq. (4.1)]. \(\gamma = 0\) implies \(|\gamma| = r\).

B. Phase \(N = 0\), \(Q^{(0)} = \pi/b\)

We now consider the case \(N = 0\) with \(Q^{(0)} = \pi/b\), which corresponds to the phase \(N = 0\) terminating the cascade. There is only one SDW in that case, so we can choose \(\Delta_a^{(0)} = \Delta_a^{(0)}\) (alternatively, we could choose \(\Delta_a^{(0)} = 0\)). The free energy is then given by
\[
F_0 = 4 \sum_a \left[A_0 |\Delta_a^{(0)}|^2 + B \Delta_a^{(0)} \Delta_a^{(0)*} + 2K |\Delta_a^{(0)}|^4\right].
\]  

(4.26)
The quadratic part of the free energy $F_0^{(2)}$ is diagonalized by introducing the order parameters $u$ and $v$ defined by

$$\begin{pmatrix} \Delta^{(0)}_{++} \\ \Delta^{(0)}_{+-} \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix}. \tag{4.27}$$

This leads to

$$F_0^{(2)} = 4\lambda_1^{(0)}|u|^2 + 4\lambda_2^{(0)}|v|^2. \tag{4.28}$$

with

$$\lambda_1^{(0)} = \frac{1}{I_0} \left( \frac{1}{g_3 + g_3} - \chi^{(0)}(Q_0) \right), \tag{4.29}$$

$$\lambda_2^{(0)} = \frac{1}{I_0} \left( \frac{1}{g_3 - g_3} - \chi^{(0)}(Q_0) \right).$$

$T_c$ is determined by $\lambda_1^{(0)} = 0$, i.e., $1 - (g_3 + g_3)\chi^{(0)}(Q_0) = 0$. This agrees with the RPA result (2.18) when $\chi^{(0)}(Q_N) = \chi^{(0)}(Q_0)$.

Since $\lambda_2^{(0)} > \lambda_1^{(0)}$, $v = 0$ for $T \leq T_c$. This implies $\Delta_{++}^{(0)} = \Delta_{+-}^{(0)}$. Thus, the phase $N = 0$, $Q_x = \pi/b$ is always linearly polarized. For $N = 0$ and $Q_x^{(0)} = \pi/b$, $g_3$ couples $\Delta_++^{(0)}$ and $\Delta_{+-}^{(0)}$. As a result, we cannot have $\Delta_++^{(0)} \neq 0$ and $\Delta_{+-}^{(0)} = 0$, so that the polarization cannot be circular. The case $g_3 = 0$ is special since then $\lambda_1^{(0)} = \lambda_2^{(0)}$ and both $u$ and $v$ become non-zero below $T_c$. Nevertheless, Eq. (4.26) shows that the sinusoidal wave is more stable than the helicoidal wave in this case too.

Setting $v = 0$, we obtain the free energy

$$F_0 = 4\lambda_1^{(0)}|u|^2 + 4K|u|^4. \tag{4.30}$$

Minimizing $F_0$ with respect to $u$, we obtain

$$|u|^2 = -\frac{\lambda_1^{(0)}}{2K}, \quad F_0 = -\frac{(\lambda_1^{(0)})^2}{K}. \tag{4.31}$$

$V. \ SPECTRUM$

In the absence of umklapp processes, the spectrum consists of Landau subbands separated by gaps opening at the Fermi level, and at $n\alpha_f/2$ (integer) above and below the Fermi level.\textsuperscript{1,5-7} In this section we show that for sinusoidal SDW’s the gaps opening at the Fermi level depend on the transverse momentum $k_y$ (in this section, we use a gauge where $k_x$ is a good quantum number). On the other hand, the spectrum of the helicoidal phase remains independent of $k_y$. As shown below, this provides a natural explanation of the instability of the sinusoidal phase with respect to the helicoidal phase.

In this section we use the gauge $\mathbf{A} = (0, Hx, 0)$ where the calculations are simpler. In the next section this will also allow us to calculate the QHE using previous results derived in this gauge. Using the Peierls substitution, we obtain

$$\mathcal{H}_0 = \sum_{\alpha, \sigma, k_y} \int dx \tilde{\psi}_{\alpha \sigma}(x, k_y)[(uvF_{-i\alpha \sigma \kappa} - k_F)$$

$$+ t_{\pm}(k_y, b - Gx) + \sigma \mu_B H] \tilde{\psi}_{\alpha \sigma}(x, k_y), \tag{5.1}$$

where we have taken the Fourier transform with respect to the $y$ direction. In the absence of electron-electron interaction, the eigenstates and the spectrum are given by

$$\phi_k^{\alpha}(r) = \frac{1}{\sqrt{S}} e^{i\mathbf{k} \cdot \mathbf{r} + i(\alpha \omega_v)T_x(k_y, b - Gx), \tag{5.2}$$

$$\epsilon_k^{\alpha \sigma} = uv_F(\alpha k_x - k_F) + \sigma \mu_B H.$$  

The dispersion law is now one-dimensional and the states are extended in both the $x$ and $y$ directions. However, since the energy does not depend on $k_y$, we can take the Fourier transform with respect to $k_y$ and obtain localized wave functions similar to those obtained in Sec. II. The Wannier-Stark ladder can then be recovered by a simple gauge transformation.

Using Eq. (4.1), the interacting part of the mean-field Hamiltonian can be written as

$$\mathcal{H}^{\text{MF}} = \sum_{\alpha, k_y} \int dx e^{-i\alpha Q_x^{(N)}} \tilde{\Delta}^{(N)}_{\alpha \kappa} \tilde{\psi}_{\alpha f}(x, k_y) \tilde{\psi}_{\alpha f}(x, k_y + \alpha Q_x^{(N)}) + e^{i\alpha Q_x^{(N)}} \tilde{\Delta}^{(N)}_{\alpha \kappa} \tilde{\psi}_{\alpha f}(x, k_y) \tilde{\psi}_{\alpha f}(x, k_y + \alpha Q_x^{(N)})] + \text{H.c.} \tag{5.3}$$

up to a constant term. Introducing new fields $\overline{\psi}_{\alpha f}$ defined by

$$\psi_{\alpha f}(x, k_y) = e^{i\alpha k_x - i\alpha \sigma \mu_B H/2} \psi_{\alpha f}(x, k_y), \tag{5.4}$$

we rewrite the Hamiltonian as

$$\mathcal{H}^{\text{MF}} = \sum_{\alpha, \sigma, k_y} \int dx \overline{\psi}_{\alpha f}(x, k_y)(-i \alpha v_F \partial_x) \overline{\psi}_{\alpha f}(x, k_y) - \sum_{\alpha, \sigma, k_y, n} \int dx e^{-i\alpha N G x - i\alpha n(k_y b - Gx + \alpha Q_x^{(N)} b/2)}$$

$$\times \left[ \tilde{\Delta}^{(N)}_{\alpha f} I_n(Q_x^{(N)}) \tilde{\psi}_{\alpha f}(x, k_y) \tilde{\psi}_{\alpha f}(x, k_y + \alpha Q_x^{(N)}) + \tilde{\Delta}^{(N)}_{\alpha f} I_n(Q_x^{(N)}) \tilde{\psi}_{\alpha f}(x, k_y) \tilde{\psi}_{\alpha f}(x, k_y + \alpha Q_x^{(N)}) + \text{H.c.} \right]. \tag{5.5}$$

We have used

$$\sum_{n = -\infty}^{\infty} I_n(q_s) e^{-i n(u + q_s b/2)} = e^{i u (u + q_s b)} \int T_x(u + q_s b) + T_x(u) + T_x(u + q_s b), \tag{5.6}$$
which follows from Eq. (2.11). To proceed further, we use the QLA. This amounts to retaining only the gaps that open at the Fermi level neglecting those opening above and below the Fermi level. In the QLA, only the term $n = N$ is retained in Eq. (5.5). This leads to

$$\mathcal{H}^{\text{MF}}_{\text{int}} = -\sum_{\alpha, k_y} \int dx e^{-i\alpha N k_y b} \tilde{\Delta}_{\alpha}^{(N)} \tilde{\psi}^\dagger_{\alpha}(x, k_y - \alpha Q_y^N/2) \tilde{\psi}_{\alpha}(x, k_y + \alpha Q_y^N/2)$$

$$+ \tilde{\Delta}_{\alpha}^{(N)} \tilde{\psi}^\dagger_{\alpha}(x, k_y - \alpha Q_y^N/2) \tilde{\psi}_{\alpha}(x, k_y + \alpha Q_y^N/2) + \text{h.c.}$$

(5.7)

In the case of sinusoidal SDW’s, Eq. (5.7) shows that $k_y$ is coupled to $k_y \pm Q_y^N$, $k_y \pm 2Q_y^N$, \ldots, so that the Hamiltonian cannot be straightforwardly diagonalized. For very small $g_3$, the system is not significantly affected by umklapp processes (the SDW with wave vector $Q_x$ has a very small amplitude), and therefore we expect that the spectrum will not be very sensitive to $g_3$. Thus, the most interesting situation arises when umklapp processes are strong enough so that the FISDW phase becomes commensurate in the transverse direction ($Q_y^N = \pi b$) (which implies that $N$ is even). In that case, $k_y$ is coupled only to $k_y + \pi/b$, and both the sinusoidal and helicoidal phases are described by the Hamiltonian

$$\mathcal{H}_{\text{MF}} = \sum_{k_x, k_y} \left( \tilde{\psi}^\dagger_{+}(k_x, k_y + \pi/2b), \tilde{\psi}^\dagger_{-}(k_x, k_y - \pi/2b) \right)$$

$$\times \left( v_F K_x - e^{-iNk_y b} \tilde{\Delta}_{+}^{(N)} - e^{-iNk_y b} \tilde{\Delta}_{+}^{(N)\dagger} \right) \left( \tilde{\psi}_{+}(k_x, k_y + \pi/2b) \right)$$

$$+ \sum_{k_x, k_y} \left( \tilde{\psi}^\dagger_{+}(k_x, k_y - \pi/b), \tilde{\psi}^\dagger_{-}(k_x, k_y + \pi/b) \right)$$

$$\times \left( v_F K_x - e^{-iNk_y b} \tilde{\Delta}_{-}^{(N)} - e^{-iNk_y b} \tilde{\Delta}_{-}^{(N)\dagger} \right) \left( \tilde{\psi}_{+}(k_x, k_y - \pi/2b) \right),$$

(5.8)

where $K_x$ is now measured with respect to $\pm k_F \pm \mu_B H/v_F$. In the metallic phase, the dispersion law is given by $\epsilon_1 = \pm v_F K_x$, $\epsilon_2 = \pm v_F K_y$. The $+/-$ corresponds to right/left moving electrons and the degeneracy is due to spin. In the SDW phase, gaps open at the Fermi level, and the dispersion law becomes $E_1 = \pm \left[ v_F^2 K_x^2 + \Delta_1(k_y)^2 \right]^{1/2}$ and $E_2 = \pm \left[ v_F^2 K_x^2 + \Delta_2(k_y)^2 \right]^{1/2}$ with

$$\Delta_1(k_y)^2 = \left| e^{-iNk_y b} \tilde{\Delta}_{+}^{(N)} + e^{iNk_y b} \tilde{\Delta}_{+}^{(N)\dagger} \right|^2$$

$$= \left| \tilde{\Delta}_{+}^{(N)\dagger} \right|^2 + \left| \tilde{\Delta}_{+}^{(N)} \right|^2 + \left| 2 \tilde{\Delta}_{+}^{(N)} \cos(2Nk_y b + \varphi_1) \right|,$$

$$\Delta_2(k_y)^2 = \left| e^{-iNk_y b} \tilde{\Delta}_{-}^{(N)} + e^{iNk_y b} \tilde{\Delta}_{-}^{(N)\dagger} \right|^2$$

$$= \left| \tilde{\Delta}_{-}^{(N)\dagger} \right|^2 + \left| \tilde{\Delta}_{-}^{(N)} \right|^2 + \left| 2 \tilde{\Delta}_{-}^{(N)} \cos(2Nk_y b + \varphi_2) \right|,$$

(5.9)

where $\varphi_1$ and $\varphi_2$ depend on the phases of $\tilde{\Delta}_{\pm}^{(N)}$.

### A. Sinusoidal waves

For sinusoidal waves, as follows from Eq. (5.9), there are interferences between the two SDW’s, and the dispersion depends on $k_y$. Using $|\Delta_{\pm}^{(N)}|^2/|\Delta_{\pm}^{(N)}| = |\tan(\vartheta_0)|$ [Eq. (4.24)], we obtain

$$\left| \Delta_1(k_y) \right|_{\text{min}} \leq \left| \Delta_2(k_y) \right|_{\text{min}} \leq 1 - |\tan(\vartheta_0)|$$

$$\left| \Delta_1(k_y) \right|_{\text{max}} \leq \left| \Delta_2(k_y) \right|_{\text{max}} \leq 1 + |\tan(\vartheta_0)|.$$  (5.10)

For $|\vartheta_0| \ll 1$, which corresponds to a large $t_{ab}$ (Sec. II), $|\Delta_1(k_y)| \ll |\Delta_2(k_y)|$. The dispersion in the transverse direction is weak. Everywhere on the Fermi surface, the gap is of the order of $|\Delta_{+}^{(N)}| = |\Delta_{-}^{(N)}|$. For larger values of $|\vartheta_0|$, the dispersion becomes significant. In particular, when $|\vartheta_0| = \pi/4$ (which occurs when there is a degeneracy between $N$ and $-N$, i.e., when $t_{ab} = 0$), we have $|\Delta_{-}^{(N)}| = |\Delta_{+}^{(N)}|$ and the spectrum becomes gapless.\textsuperscript{26} Equations (5.9) show that there are $4N$ values of $k_y$ for which $\Delta_1$ or $\Delta_2$ vanish.

However, the occurrence of the helicoidal phase prevents the spectrum from becoming gapless. Indeed, the stability of the sinusoidal phase requires $\sin^2(2\vartheta_0)/2 < 3$. From Eq. (5.10), we then deduce

$$\left| \Delta_1(k_y) \right|_{\text{min}} \leq 0.32.$$  (5.11)

### B. Helicoidal waves

For helicoidal waves, $\Delta_{+}^{(N)} = \Delta_{-}^{(N)} = 0$. The spectrum is given by $E_1 = \pm \left[ v_F^2 K_x^2 + |\Delta_{+}^{(N)}|^2 \right]^{1/2}$ and $E_2 = \pm \left[ v_F^2 K_x^2 + |\Delta_{-}^{(N)}|^2 \right]^{1/2}$. Contrary to the sinusoidal phase, the gaps at the Fermi level, $\Delta_{+}^{(N)}$ and $\Delta_{-}^{(N)}$, remain independent of the
transverse momentum \( k_y \). Since the sinusoidal phase becomes gapless at \( |\phi N| = \pi / 4 \), it is natural to expect that, above a certain value of \( |\phi N| \), the system prefers to form helicoidal SDW’s in order to lower the free energy by opening a large gap on the whole Fermi surface. This precisely the result we have obtained in Sec. IV by considering the Ginzburg-Landau expansion of the free energy.

In general, the two gaps \( |\tilde{\Delta}^{(N)}_+| \) and \( |\tilde{\Delta}^{(N)}_-| \) differ (they are equal only when \( t_{bg} = 0 \) or \( N = 0 \)). As shown in Sec. VII, this property gives rise to a kinetic magnetoelectric effect.

### VI. QUANTUM HALL EFFECT

In this section, we use the results of Ref. 9 to study the quantum Hall effect. At zero temperature, the off-diagonal conductivity is given by the formula

\[
\sigma_{xy} = -ie^2 \sum_{k_x, k_y} \frac{d k_x}{2\pi} \frac{d k_y}{2\pi} (\partial_{k_x} \langle \psi_\alpha | \partial_{k_x} | \psi_\alpha \rangle - \partial_{k_y} \langle \psi_\alpha | \partial_{k_y} | \psi_\alpha \rangle).
\]

The summation is taken over all completely occupied bands and the integral is taken over the Brillouin zone. \( |\psi_\alpha(k_x, k_y)\rangle \) are the normalized eigenvectors of the Hamiltonian.

Before calculating \( \sigma_{xy} \) in the FISDW phases, we recall the main result of Ref. 9 and generalize it to the case of two SDW’s. We consider the Hamiltonian

\[
\mathcal{H}_{MF} = \sum_{k_x, k_y} (\tilde{\psi}_{k_x, k_y}^\dagger \psi_{k_x, k_y}) + \sum_{k_x, k_y} \frac{1}{2} \left( \begin{array}{c} \tilde{\psi}_{k_x, k_y} \\ \psi_{k_x, k_y} \end{array} \right) \left( \begin{array}{cc} e^{i\phi_1(k_y)} & -ie^{i\phi_2(k_y)} \\ -ie^{-i\phi_1(k_y)} & e^{-i\phi_2(k_y)} \end{array} \right) \left( \begin{array}{c} \tilde{\psi}_{k_x, k_y} \\ \psi_{k_x, k_y} \end{array} \right)
\]

where \( \Delta_1 e^{-i\phi_1(k_y)} = \Delta_2 e^{-i\phi_2(k_y)} \).

### A. Sinusoidal waves

Comparing Eqs. (5.8) and (6.4), we deduce

\[
\Delta_1 e^{-i\phi_1(k_y)} = \Delta_2 e^{-i\phi_2(k_y)}
\]

\[
= -e^{iNk_yb} |\tilde{\Delta}^{(N)}_+| - e^{-iNk_yb} |\tilde{\Delta}^{(N)}_-|.
\]

We have used \(|\tilde{\Delta}^{(N)}_+| = |\tilde{\Delta}^{(N)}_-|\). When \( k_y \) varies from 0 to \( 2\pi/b \), the change \( \phi_1(2\pi/b) - \phi_1(0) = \phi_2(2\pi/b) - \phi_2(0) \) is determined by the term with the largest amplitude in Eq. (6.6). Since \(|\tilde{\Delta}^{(N)}_+|/|\tilde{\Delta}^{(N)}_-| = \gamma| < 0.518 \) in the sinusoidal phase, we obtain

\[
\phi_1(2\pi/b) + \phi_2(2\pi/b) - \phi_1(0) - \phi_2(0) = -4\pi N.
\]

This yields

\[
\sigma_{xy} = -2N e^2 h,
\]

where we have restored the dimensional Planck constant \( h \).

### B. Helicoidal waves

For helicoidal waves, we deduce from Eq. (5.7)

\[
\Delta_1 e^{-i\phi_1(k_y)} = -e^{iNk_yb} \tilde{\Delta}^{(N)}_+.
\]
different way, which results in a uniform magnetization redistribution of electrons affects up and down spins in a way we have not shown the Zeeman splitting.

\[ \Delta z e^{-i \phi_2(k_z)} = - e^{-i n k_z b \hat{\Sigma}^{(N)}}. \]

This yields \( \phi_1(2 \pi / b) - \phi_1(0) = - \left[ \phi_1(2 \pi / b) - \phi_1(0) \right] \) so that

\[ \sigma_{xy} = 0. \] (6.10)

Thus, we come to the conclusion that the QHE vanishes in the helicoidal phase.

VII. MAGNETOELECTRIC EFFECT

A magnetoelectric effect may exist if time-reversal and space-inversion symmetries are broken.\(^{28}\) Gor’kov and Sokol found the kinetic magnetoelectric effect for a single helicoidal SDW.\(^{29}\) The effect also exists in the presence of two helicoidal SDW’s of opposite chiralities, provided their amplitudes are not equal. An electric current \( j_x \) along the chains induces a uniform magnetization \( \delta M \) along the vector \( n \) that characterizes the spin polarization of the helicoidal SDW’s. In our case, the vector \( n \) is parallel to the magnetic field \( H \), which is oriented along the \( z \) axis, thus

\[ \delta M_z \approx j_x. \] (7.1)

Here \( \delta M_z \) is the additional spin-magnetization density induced by \( j_x \) in excess of the magnetization density \( M_z \) induced by the magnetic field without \( j_x \). The effect can be understood by considering the spectrum of electronic excitations in the helicoidal FISDW phase shown in Fig. 7. The \( +k_F \) electrons with spin up and the \( -k_F \) electrons with spin down have the energy gap \( \Delta_{N,+} \), whereas the \( +k_F \) electrons with spin down and the \( -k_F \) electrons with spin up have the different energy gap \( \Delta_{N,-} \). To produce a current \( j_x \) along the chains, electrons need to be transferred from \( -k_F \) to \( +k_F \) (we assume that the electric field is weak enough so that the SDW’s remain pinned by impurities). For \( \Delta_{N,+} \neq \Delta_{N,-} \) (\( \Delta_{N,+} \neq \Delta_{N,-} \) if \( t_{4b} \neq 0 \) and \( N \neq 0 \)), this redistribution of electrons affects up and down spins in a different way, which results in a uniform magnetization \( M_z \). Denoting the deviation of the distribution function of electrons with spin \( \sigma \) and momenta near \( a k_F \) from the equilibrium one by \( \delta n_{a,\sigma} \), we have

\[ j_z = e v_F \sum_{\sigma} \left( \delta n_{+,\sigma} - \delta n_{-,\sigma} \right), \] (7.2)

\[ \delta M_z = \frac{g \mu_B}{2} \sum_{a=\pm} (\delta n_{a,1} - \delta n_{a,-1}). \]

Here we denote the electron gyromagnetic factor by \( g \) (assumed to be equal to 2 in the preceding sections). At low temperature, \( T \ll |\Delta_{N,+}|, |\Delta_{N,-}| \), the electrons are excited solely above the lowest energy gap \( \Delta_{N,-} \) in Fig. 7. This implies that \( \delta n_{+,1} = \delta n_{-,1} = 0 \) and

\[ \frac{\delta M_z}{j_z} = - \frac{g \mu_B}{2 e v_F}. \] (7.3)

Equation (7.3) can be rewritten as

\[ \frac{\delta M_z}{\mu_B} = - \frac{g l}{2 e v_F L_y L_z}, \] (7.4)

where \( l = j_1 L_y L_z \) is the current passing through the sample of cross section \( L_y L_z \). For \( l = 1 \mu A \) [which is slightly below the critical current for the depinning of the SDW’s (Ref. 30)], \( L_y L_z \approx 1 \mathrm{mm}^2, v_F \approx 3 \times 10^{-5} \mathrm{m/s}, \) and \( g = 2 \), we obtain

\[ \frac{|\delta M_z|}{\mu_B} \approx 2 \times 10^{-15} \mathrm{\AA}^{-3}. \] (7.5)

This should be compared with the ground-state magnetization density

\[ \frac{|M_z|}{\mu_B} \approx 10^{-8} \mathrm{\AA}^{-3}, \] (7.6)

that we obtain from Ref. 7. Thus, we obtain \( |\delta M_z|/|M_z| \approx 2 \times 10^{-7} \). The reentrant phases \( N=0 \) are somehow special since \( |\Delta_{N,0}| = |\Delta_{N,-1}| \) independent of \( t_{4b} \). Consequently, these phases do not exhibit the magnetoelectric effect, although they are helicoidal.

VIII. COEXISTENCE BETWEEN SUCCESSIVE PHASES

It has been shown by Lebed’ that under certain circumstances, umklapp processes can lead to the simultaneous existence of two successive sinusoidal phases \( N+\beta \) and \( N-\gamma \). The system then evolves from the phase \( N+\beta \) to the phase \( N \) via a region of the phase diagram where both the phases \( N+\beta \) and \( N-\gamma \) exist. The transitions to the coexistence region are of second order.

In this section, we reconsider the problem of the coexistence between two successive SDW phases, distinguishing between sinusoidal and helicoidal waves. We analyze all possible cases (depending on the polarization of the SDW’s).

The coexistence of two phases implies the simultaneous formation of four SDW’s. Therefore Eqs. (4.7) and (4.10) should be replaced by
The free energy becomes

\[ F_{N,N+\beta} = F_N + F_{N+\beta} + F_{\text{int}}, \]

with the interacting part

\[
F_{\text{int}} = 2K \sum_{\alpha} \left[ |\tilde{\Delta}_{\alpha}|^2 + |\tilde{\Delta}_{\alpha}|^2 \right] + 2K \cos[(N+\beta)Q_x^{(N)}b - NQ_y^{(N+\beta)b}] \sum_{\alpha} (\tilde{\Delta}_{\alpha}^{(N)} \tilde{\Delta}_{\alpha}^{(N+\beta)} + \text{c.c.}) + \delta_{N,0} \sum_{\alpha} \delta_0^{(N)} b, a \pi K \sum_{\alpha} \left[ 2 \sum_{\beta=\pm} |\Delta_{\alpha}|^2 |\Delta_{\alpha}|^2 + \cos(\beta Q_y^{(0)b}) (|\Delta_{\alpha}|^2 + |\Delta_{\alpha}|^2) |\Delta_{\alpha}|^2 + \text{c.c.} \right].
\]

Without loss of generality, we have assumed that the phase \( N + \beta \) is not the last phase of the cascade (i.e., we do not consider the case \( N + \beta = 0 \) and \( Q^{(N+\beta)} = \pi/b \)). In order to study the possible coexistence of phases \( N \) and \( N + \beta \), we consider a region in the phase diagram where the phase \( N + \beta \) is more stable than the phase \( N + \beta \) (\( T_c^{(N)} > T_c^{(N+\beta)} \)). Assuming that the order parameters of the phase \( N + \beta \) are infinitesimal, we derive an effective free energy for this phase, from which we conclude about the coexistence of the two phases. The same reasoning is applied to regions of the phase diagram where \( T_c^{(N)} < T_c^{(N+\beta)} \).

### A. Sinusoidal waves

#### 1. \( N \neq 0 \)

Introducing the order parameters \( u^{(N)}_a, u^{(N)}_b, u^{(N+\beta)}_a \), and \( u^{(N+\beta)}_b \) defined in Sec. IV A, and setting \( u^{(N)}_a = u^{(N+\beta)}_a = 0 \), we rewrite Eq. (8.3) (for \( N \neq 0 \)) as

\[
F_{\text{int}}^{N,N+\beta} = 2K \sum_{\alpha} \left[ \cos^2(\theta_N)|u^{(N)}_a|^2 + \sin^2(\theta_N)|u^{(N)}_b|^2 \right] |\Delta^{(N+\beta)}|^2 + \sin^2(\theta_{N+\beta})|u^{(N+\beta)}|^2 \right] + 2K \cos[(N+\beta)Q_x^{(N)}b - NQ_y^{(N+\beta)b}] \sin(2\theta_N) \sin(2\theta_{N+\beta}) (u^{(N)}_a u^{(N+\beta)} + \text{c.c.}).
\]

For sinusoidal waves, we have \( |u^{(N)}_a| = |u^{(N)}_b| \) and \( |u^{(N+\beta)}_a| = |u^{(N+\beta)}_b| \). We consider a region of the phase diagram where \( T_c^{(N)} > T_c^{(N+\beta)} \) and assume that \( u^{(N+\beta)}_a \) is infinitesimal. To lowest order in \( u^{(N+\beta)}_a \), the effective free energy for the phase \( N + \beta \) is

\[
F_{\text{eff}}^{N+\beta} = 2\lambda_{N+\beta}|u^{(N+\beta)}|^2 + 4K|u^{(N)}_a|^2 |u^{(N+\beta)}|^2 \]

\[
+ K \cos((N+\beta)Q_x^{(N)}b - NQ_y^{(N+\beta)b}) \sin(2\theta_N) \sin(2\theta_{N+\beta}) (u^{(N)}_a u^{(N+\beta)} + \text{c.c.}),
\]

where \( u^{(N)}_a \) is not changed by the infinitesimal \( u^{(N+\beta)}_a \) and is therefore given by Eq. (4.20) for \( T \leq T_c^{(N)} \). The free energy is minimal if the phase of \( u^{(N+\beta)}_a \) is such that

\[
\cos((N+\beta)Q_x^{(N)}b - NQ_y^{(N+\beta)b}) \sin(2\theta_N) \sin(2\theta_{N+\beta}) u^{(N)}_a u^{(N+\beta)} + \text{c.c.} = 0.
\]

which yields

\[
F_{\text{eff}}^{N+\beta} = 2|u^{(N+\beta)}|^2 [\lambda_{N+\beta} + 2K|u^{(N)}_a|^2 - K|u^{(N)}_b|^2 |\cos((N+\beta)Q_x^{(N)}b - NQ_y^{(N+\beta)b}) \sin(2\theta_N) \sin(2\theta_{N+\beta}) |].
\]
A second-order phase transition to a phase where both \( u^{(N)} \) and \( u^{(N+\beta)} \) are nonzero occurs if the coefficient of \( |u^{(N+\beta)}|^2 \) in \( F_{N+\beta} \) becomes negative. Since in all cases, \( Q_y^{(N+\beta)} - \pi b \) (see Sec. II), we make the approximation \( \cos((N+\beta)Q_y^{(N)}b-NQ_y^{(N+\beta)}b)=1 \). Using (see Appendix C)

\[
\lambda_1^{(N)} = \frac{N(0)}{2T_c}(T-T_c^{(N)}),
\]

we can write the coexistence condition for \( T \leq T_c^{(N+\beta)} \) as

\[
\frac{T-T_c^{(N+\beta)}}{T_c^{(N+\beta)}} = \frac{T-T_c^{(N)}}{T_c^{(N)}} x_+ ,
\]

where

\[
x_+ = \frac{2 - |\sin(2\theta_N)\sin(2\theta_{N+\beta})|}{1 + (1/2)\sin^2(2\theta_N)}.
\]

For the coexistence in regions of the phase diagram where \( T_c^{(N)} < T_c^{(N+\beta)} \), we obtain by the same method the condition (for \( T \leq T_c^{(N+\beta)} \))

\[
\frac{T-T_c^{(N)}}{T_c^{(N)}} \leq \frac{T-T_c^{(N+\beta)}}{T_c^{(N+\beta)}} x_+ ,
\]

where

\[
x_+ = \frac{2 - |\sin(2\theta_N)\sin(2\theta_{N+\beta})|}{1 + (1/2)\sin^2(2\theta_N)}.
\]

\( \theta_N, \theta_{N+\beta} \) are determined by \( A_N, A_N, \) and \( B, \) and therefore depend on temperature and magnetic field. To verify that the region of the phase diagram defined by Eqs. (8.9) and (8.11) exists, we consider a point in the \((H,T)\) plane slightly below the intersection point of the two curves \( T_c^{(N)} \) and \( T_c^{(N+\beta)} \). For this point \( T_c^{(N)} = T_c^{(N+\beta)} \) and the coexistence conditions can be rewritten as

\[
(1-x) \frac{T-T_c^{(N)}}{T_c^{(N)}} \leq 0 ,
\]

where \( x = x_+ x_- \). Since \( T-T_c^{(N)} < 0 \), the coexistence is possible only if \( x_- < 1 \) or \( x_+ < 1 \). The existence of linearly polarized SDW’s requires \( \sin^2(2\theta_N)\sin^2(2\theta_{N+\beta}) < 2/3 \) and therefore implies \( x_- _{\max} = x_+ _{\min} = 1 \). Consequently, there is no coexistence between phases for sinusoidal waves. Thus, our results invalidate Lebed’s conclusion\(^{17}\) concerning the coexistence of two successive sinusoidal phases.

If we discard the existence of helicoidal waves, then the coexistence between phases may be possible depending on the geometry of the Fermi surface. Let us take for instance \( Q_y^{(N)} = Q_y^{(N+\beta)} = \pi b / 2 \) and \( t_{ab} = 0 \), which is the case considered by Lebed. Then \( \theta_N = \theta_{N+\beta} = \pi / 4 \). The region of coexistence does exist and is determined by

\[
\frac{3}{2} \frac{T-T_c^{(N+\beta)}}{T_c^{(N+\beta)}} = \frac{T-T_c^{(N)}}{T_c^{(N)}}, \quad \frac{2}{3} \frac{T-T_c^{(N+\beta)}}{T_c^{(N+\beta)}} < \frac{T-T_c^{(N)}}{T_c^{(N)}}.
\]

This is precisely the result obtained by Lebed.\(^{17}\)

2. \( N=0, Q_y^{(0)} = \pi / b \)

We can study the coexistence of the last two phases of the cascade following the same procedure. Using the result of Sec. IV B, we have

\[
F_{0,\beta}^{\text{int}} = 8K|u_{+}^{(0)}|^2 + 2K \cos(\beta \pi) \sin(2\theta_N)(u_{+}^{(0)} u_{+}^{(0)} + c.c.).
\]

Choosing the phases of \( u_{+}^{(0)} \) and \( u_{+}^{(0)} \) in order to minimize the free energy, we obtain

\[
F_{0,\beta}^{\text{int}} = 4K[2 - |\sin(2\theta_N)|]|u_{+}^{(0)}|^2.
\]

We deduce that the coexistence region is determined by

\[
\frac{1}{x_+} T_c^{(0)} T_c^{(0)} T_c^{(0)} T_c^{(0)} \leq \frac{T-T_c^{(0)}}{T_c^{(0)}} \leq \frac{T-T_c^{(0)}}{T_c^{(0)}},
\]

where

\[
x_+ = \frac{2 - |\sin(2\theta_N)|}{1 + (1/2)\sin^2(2\theta_N)}.
\]

The coexistence occurs if \( x_+ < 1 \) or \( x_- < 1 \). Since \( \sin^2(2\theta_N) < 2/3 \), \( x_- _{\max} = 0.89 \). In principle, the coexistence between the phases \( N=\beta \) and \( N=0, Q_y = \pi b \) is therefore possible in the region of the phase diagram where \( T_c^{(0)} > T_c^{(0)} \) provided that \( x_- < 1 \). If \( \beta=1 \), then our numerical calculations show that \( \sin^2(2\theta_N) < 2/3 \) (the latter inequality holds for all phases with \( N \) odd). Therefore, the coexistence region does not exist if the phase \( N=0 \) is preceded by the phase \( \beta=1 \). In the case where the phase \( N=0 \) is preceded by the phase \( \beta=2 \), the coexistence region exists provided that \( x_- < 1 \). This situation however requires strong umklapp scattering and is therefore quite unlikely. [Note that for \( \sin^2(2\theta_N)=1 \), Eq. (8.17) agrees with Lebed’s results.]\(^{17}\)

3. \( N+\beta=0, Q_y^{(N+\beta)} \neq \pi / b \)

The coexistence between the phase \( N \) and the reentrant phase \( N+\beta=0, Q_y^{(N+\beta)} \neq \pi / b \) can be studied by setting \( \beta = -N \). This case is special since the phase \( N+\beta=0 \), \( Q_y^{(N+\beta)} \neq \pi / b \) is always helicoidal when \( g_3 \neq 0 \) (see Sec. IV). Using \( |u_{+}^{(N)}| = |u_{-}^{(N)}| \) and \( u_{+}^{(0)} = 0 \), we have

\[
F_{N,0}^{\text{int}} = 2K|u_{+}^{(0)}|^2.
\]

In the region \( T_c^{(N)} < T_c^{(0)} \), we find the effective free energy for the phase \( N \) (for \( T<T_c^{(0)} \))

\[
F_{N}^{\text{eff}} = |u_{+}^{(N)}|^2 N(0) \left[ \frac{T-T_c^{(N)}}{T_c^{(N)}} - 2 \frac{T-T_c^{(0)}}{T_c^{(0)}} \right].
\]
The coefficient of $|u_+^{(N)}|^2$ is always positive so that there is no phase coexistence. In the region $T_c^{(0)} < T_c^{(N)}$, we find the effective free energy (for $T < T_c^{(N)}$)

$$F_0^{\text{eff}} = |u_+^{(N)}|^2 \frac{N(0)}{2} \left[ \frac{T - T_c^{(0)}}{T_c^{(0)}} - \frac{2}{1 + (1/2)\sin^2(2\theta_N)} \frac{T - T_c^{(N)}}{T_c^{(N)}} \right].$$

(8.21)

which shows that there is no coexistence.

B. Helicoidal waves

1. $N \neq 0$, or $N = 0$ and $Q_y^{(N)} \neq \pi/b$

First we study the coexistence between the two helicoidal phases $N$ and $N + \beta$. For simplicity, we consider only the case $\theta_N = \theta_{N+\beta} = \pi/4$. For helicoidal waves, we have $u_+^{(N)} = 0$ and $u_+^{(N+\beta)} = 0$ (we could also choose $u_+^{(N+\beta)} = 0$, this would not change the result). Equation (8.3) then yields

$$F_{N=0, \beta}^{\text{int}} = K |u_+^{(N)}|^2 |u_+^{(N+\beta)}|^2. \quad (8.22)$$

In the region $T_c^{(N)} > T_c^{(N+\beta)}$, we find the effective free energy for the phase $N + \beta$ (for $T < T_c^{(N)}$)

$$F_{N+\beta}^{\text{eff}} = |u_+^{(N+\beta)}|^2 \frac{N(0)}{2} \left[ \frac{T - T_c^{(N+\beta)}}{T_c^{(N+\beta)}} - \frac{2}{1 + (1/2)\sin^2(2\theta_N)} \frac{T - T_c^{(N)}}{T_c^{(N)}} \right].$$

(8.23)

which shows that there is no coexistence.

2. $N = 0$, $Q_y = \pi/b$

For the coexistence between the helicoidal phase $N = \beta$ and the sinusoidal phase $N = 0$, $Q_y = \pi/b$ terminating the cascade, we have

$$F_{0, \beta}^{\text{int}} = 4K |u_+|^2 |u_-|^2. \quad (8.25)$$

This yields (for $T < T_c^{(0)}$)

$$F_{\beta}^{\text{eff}} = |u_-|^2 \frac{N(0)}{2} \left[ \frac{T - T_c^{(\beta)}}{T_c^{(\beta)}} - \frac{2}{1 + (1/2)\sin^2(2\theta_N)} \frac{T - T_c^{(0)}}{T_c^{(0)}} \right].$$

(8.26)

in the region $T_c^{(0)} > T_c^{(\beta)}$, and (for $T < T_c^{(0)}$)

$$F_0^{\text{eff}} = 4 |u_-|^2 \frac{N(0)}{2} \left[ \frac{T - T_c^{(0)}}{T_c^{(0)}} - \frac{2}{1 + (1/2)\sin^2(2\theta_N)} \frac{T - T_c^{(\beta)}}{T_c^{(\beta)}} \right].$$

(8.27)

in the region $T_c^{(0)} < T_c^{(\beta)}$. The coexistence is therefore not possible.

IX. SUMMARY AND CONCLUSION

Our main results can be summarized as follows:

In the presence of umklapp processes, the instability of the metallic phase at the temperature $T_c^{(N)}$ corresponds to the formation of two SDW’s, with quantized longitudinal wave vectors $Q_x^{(N)} = 2k_F + NG$ and $Q_y^{(N)} = 2k_F - NG$. For very weak umklapp scattering, both SDW’s are incommensurate in the transverse direction ($Q_y = -Q_y^{(N)} \neq \pi/b$) except when $N = 0$. If we label each phase by the integer $N$ corresponding to the SDW with the largest amplitude, we have $\text{sgn}(N) = \text{sgn}(t_{2b})$. The amplitude of the SDW at wave vector $Q_y$ is vanishingly small. The quantum Hall conductivity is determined by the SDW with the largest amplitude, i.e., $\sigma_{xy} = -2Ne^2/h$.

For even $N$, there exists a critical value of $g_3$ (typically $g_3/g_2$ of the order of a few percent) above which the system prefers to form two transversely commensurate SDW’s ($Q_y^{(N)} = -Q_y^{(N)} = \pi/b$). When $t_{2b} \neq 0$, the SDW with the largest amplitude is then determined by $\text{sgn}(N) = -\text{sgn}(t_{2b})$: the QHE changes sign. The two SDW’s have comparable amplitudes when $t_{2b}$ is not too large ($t_{2b} \approx 1.5$ K). When the umklapp scattering strength increases, the first negative phase to appear is the phase $N = -2$.

Umklapp scattering also tends to suppress the phases with an odd $N$ and produce some reentrances of the phase $N = 0$ within the cascade. Unlike the last phase of the cascade, the reentrant phases $N = 0$ are incommensurate ($Q_y \neq \pi/b$).

The negative phases are likely to become helicoidal when the umklapp scattering strength is further increased. Experimentally, this situation could be achieved by decreasing pressure. The appearance of these helicoidal phases is entirely controlled by $t_{4ab}$. The QHE vanishes in the helicoidal phases, but a magnetoelastic effect appears. These two characteristic properties may be utilized to detect the helicoidal phases experimentally. The reentrant phases $N = 0$ are always helicoidal but do not exhibit the magnetoelastic effect.

In the sinusoidal phases, umklapp processes modulate the gap on the Fermi surface as a function of $k_F$. When $|\Delta(k_F)|_{\text{max}}/|\Delta(k_F)|_{\text{min}} = 0.32$, the sinusoidal phase becomes unstable against the formation of a helicoidal phase.

The conclusion of Lebed” that, in the presence of umklapp scattering, adjacent FISDW phases are separated by two second-order phase transitions and an intermediate phase with coexistence of four SDW’s is incorrect, because he did not consider helicoidal SDW’s.

In conclusion, the consideration of umklapp scattering naturally explains the appearance of negative FISDW phases in quasi-one-dimensional organic conductors. These phases are characterized not only by a sign reversal of the QHE, but also but the simultaneous presence of two SDW’s with comparable amplitudes (provided that $t_{4b}$ is not too large). This leads to the possible stabilization of helicoidal phases. But even in the sinusoidal phases (which are the ones that have been observed up to now), we expect the presence of two SDW’s to give rise to different physical properties.

APPENDIX A

We calculate in this appendix the pairing amplitudes

\[
\Delta_{\alpha 0}(w_1,w_2) = \int d^2r \phi_{w_1}^\alpha (r) \phi_{w_2}^\alpha (r) \Delta_{\alpha 0}(r)
\]

\[
= \sum_{p=-m}^m \int d^2r \phi_{w_1}^\alpha (r) \phi_{w_2}^\alpha (r) (g_2 \Delta_{\alpha 0}^{(pN)} e^{-i\alpha Q_{pN} r} + g_3 \Delta_{\alpha 0}^{(pN)} e^{-i\alpha k_{pN} + i\alpha Q_{pN} r}). \tag{A1}
\]

Using \(-4k_p + Q_x^{(pN)} = -Q_y^{(pN)}\) and \(Q_y^{(pN)} = -Q_y^{(pN)}\), we have

\[
\Delta_{\alpha 0}(w_1,w_2) = \sum_{p=-m}^m (g_2 \Delta_{\alpha 0}^{(pN)} + g_3 \Delta_{\alpha 0}^{(pN)}) \int d^2r \phi_{w_1}^\alpha (r) \phi_{w_2}^\alpha (r) e^{-i\alpha Q_{pN} r}. \tag{A2}
\]

Using Eq. (2.11), we have

\[
\int d^2r \phi_{w_1}^\alpha (r) \phi_{w_2}^\alpha (r) e^{-i\alpha Q_{pN} r} = \frac{1}{L_x} \int dx e^{ix(-k_{1x} + k_{2x} - \alpha Q_{pN})} \sum_m j_{1m}^\alpha f_{2m}^\alpha e^{-i\alpha Q_{y}^{(pN)} bm}
\]

\[
= \delta_{k_{1x} + k_{2x} + \alpha Q_{pN}} e^{-i\alpha Q_{pN} b(l_1 + l_2)} I_{a(l_1 - l_2)}(\alpha Q_{y}^{(pN)}). \tag{A3}
\]

Since \(I_n(q_y) = I_n(-q_y)\), Eq. (A3) leads to Eq. (4.7).

APPENDIX B

In this appendix, we give the main steps in the calculation of the fourth-order term of the free energy leading to Eqs. (4.13) and (8.3). We consider the case where there are simultaneously four SD’s at wave vectors \(Q_N\), \(Q_N + \beta\), \(Q_{N+\beta}\), \(Q_{N+\beta}\) :

\[
F_N^{(4)} = K \sum_{\alpha} \sum_{p_1,\ldots,p_4 = \pm \gamma_1,\ldots,\gamma_4} \sum_{n=0} \Delta_{\alpha 1}^{(p_1(N + \gamma_1))} \Delta_{\alpha 1}^{(p_2(N + \gamma_2))} \Delta_{\alpha 1}^{(p_3(N + \gamma_1))} \Delta_{\alpha 1}^{(p_4(N + \gamma_2))} \times \exp(i(b/2) [p_1(N + \gamma_1)Q_y^{(p_1(N + \gamma_1))} - 2p_1(N + \gamma_1) - p_2(N + \gamma_2)]Q_y^{(p_2(N + \gamma_2))})
\]

\[
+ \{2p_1(N + \gamma_1) - 2p_2(N + \gamma_2) + p_3(N + \gamma_1) + p_4(N + \gamma_2)\}Q_y^{(p_3(N + \gamma_3))} - p_4(N + \gamma_4)Q_y^{(p_4(N + \gamma_4))}) \times \delta_{p_1 - p_2 + p_3 - p_4\beta} \delta_{p_1 - p_2 - p_3 + p_4\beta} \delta_{p_1 - p_2 + p_3 - p_4\beta} \delta_{p_1 - p_2 - p_3 + p_4\beta} \Delta_{\alpha 1}^{(p_3(N + \gamma_3))} - \Delta_{\alpha 1}^{(p_4(N + \gamma_4))} + \Delta_{\alpha 1}^{(p_3(N + \gamma_3))} - \Delta_{\alpha 1}^{(p_4(N + \gamma_4))} + \cos(\beta Q_y b)[(\Delta_{\alpha 1}^{(0)})^2 + (\Delta_{\alpha 1}^{(0)})^2 \Delta_{\alpha 1}^{(0)} + c.c.]. \tag{B1}
\]

We write \(F_N^{(4)} = F_N^{(4)} + F_N^{(4)} + F_N^{(4)} + F_N^{(4)}\). \(F_N^{(4)}\) corresponds to the case where all the \((p_i, \gamma_i)\) in Eq. (B1) are identical \((p_1 = p_2 = \ldots = \gamma_1 = \gamma_2 = \ldots)\). \(F_N^{(4)}\) corresponds to the case where three of the \((p_i, \gamma_i)\) are equal and different from the fourth one... \(F_N^{(4)}\) corresponds to the case where all the \((p_i, \gamma_i)\) are different. Skipping the details of the calculation, we only give the final result for \(F_N^{(4)}\):

\[
F_N^{(4)} = \frac{K}{2} \sum_{\alpha, p, \gamma} |\Delta_{\alpha 1}^{(p(N + \gamma))}|^4,
\]

\[
F_N^{(4)} = \delta_{\alpha 0} \left( \sum_n \delta_{Q_y^{(0)} b_n} \right) K \sum_{\alpha} \left[ |\Delta_{\alpha 1}^{(0)}|^2 |\Delta_{\alpha 1}^{(0)}|^2 + |\Delta_{\alpha 1}^{(0)}|^2 |\Delta_{\alpha 1}^{(0)}|^2 + c.c. \right],
\]

\[
F_N^{(4)} = K \sum_{\alpha} \sum_{p, \gamma \neq p'} |\Delta_{\alpha 1}^{(p(N + \gamma))} |^2 + \delta_{\alpha 0} \left( \sum_n \delta_{Q_y^{(0)} b_n} \right) K \sum_{\alpha} \left[ 2 \sum_p |\Delta_{\alpha 1}^{(p\beta)}|^2 |\Delta_{\alpha 1}^{(p\beta)}|^2 + \frac{1}{2} (|\Delta_{\alpha 1}^{(0)}|^2 |\Delta_{\alpha 1}^{(0)}|^2 + c.c.) \right],
\]

\[
F_N^{(4)} = 2K \cos((N + \beta)Q_y b - NQ_y^{(N + \beta)} b) \sum_{\alpha} (\Delta_{\alpha 1}^{(N)} |\Delta_{\alpha 1}^{(N)}|^2 |\Delta_{\alpha 1}^{(N + \beta)}|^2 |\Delta_{\alpha 1}^{(N + \beta)}|^2 + c.c.). \tag{B2}
\]
APPENDIX C

In this appendix, we calculate $\lambda_1^{(N)}$ for $T=T_e^{(N)}$. Since $\lambda_1^{(N)}$ vanishes for $T=T_e^{(N)}$, we have

$$
\lambda_1^{(N)} = (T-T_e^{(N)}) \frac{\partial \chi_1^{(N)}}{\partial T} \bigg|_{T_e^{(N)}}
= (T-T_e^{(N)}) \frac{\partial}{\partial T} \left( \frac{N_0^2}{2} + \frac{2}{\pi} \text{sgn}(\lambda - \lambda_0) \right)
\times \left( \frac{N_0^2}{2} + 4B^2 \right)^{1/2}.
$$

From Eq. (2.19) we deduce $\partial B/\partial T=0$ and

$$
A_N = A_N |_{T_e^{(N)}} = \frac{T-T_e^{(N)}}{I_N^2} \frac{\partial \chi_1^{(N)}}{\partial T} |_{T_e^{(N)}},
$$

with

$$
\frac{\partial \chi_1^{(N)}}{\partial T} = \sum \frac{I_2^{(N)}}{I_1^{(N)}} \frac{\partial \chi_1^{(N)}}{\partial T} \left[ 2k_F + (N-n)G \right].
$$

Equation (2.10) yields

$$
\frac{\partial \chi_1^{(N)}}{\partial T} = \frac{N(0)}{2} \left[ -\frac{1}{T} + \text{Re} \left\{ \frac{i n \omega_c}{4nT^2} \Psi' \left( \frac{1}{2} + \frac{i n \omega_c}{4nT} \right) \right\} \right].
$$

where $\Psi'$ is the derivative of the digamma function. Using $\Psi'(z)=1/z + 1/2z^2$ for $|z|>1$, we obtain for $\omega_c \gg T$

$$
\frac{\partial \chi_1^{(N)}}{\partial T} = -\frac{N(0)}{2T} \delta_{n,0} + O(T/\omega_c^2).
$$

To leading order in $T/\omega_c$, we therefore have

$$
\frac{\partial \chi_1^{(N)}}{\partial T} = -\frac{T}{N(0)} \frac{N(0)}{2T},
$$

from which we deduce

$$
A_N = A_N |_{T_e^{(N)}} + \frac{N(0)}{2T_c^{(N)}} (T-T_e^{(N)}).
$$

In the same way, we can show that

$$
A_N = A_N |_{T_e^{(N)}} + \frac{N(0)}{2T_c^{(N)}} (T-T_e^{(N)}).
$$

This yields

$$
\lambda_1^{(N)} = \frac{N(0)}{2T_c^{(N)}} (T-T_e^{(N)}).
$$
